Operative technique Shoulder pieces are in stalled so that moderate Trendelenburg position can be used if desired. Many large varices remain distended when the patient is in the flat position This distention is undesirable if retrograde sclerosis is contemplated. The excess blood dilutes and 'puddles the sclerotic and causes excessive clot formation. About 10 or 15 degrees of Trendelen burg position is sufficient to drain the venous channels and is done when necessary. This appears to be more easily done than the bandaging technique of Pearce. It also leaves the legs free for secondary ligation.

The operative technique is modified from that of Pratt Local anesthesia with 1 per cent procame hydrochloride is used. A point i inch (2 5 cm.) below and 1 inch (2 5 cm.) lateral to the spine of the pubis is selected and an intradermal bleb is made (Fig 6) This spot should be over the saphenous bulb and occupies the center of the incision. In obese people the inguinal fold may be considerably below this spot. It may even be necessary as Dunlop suggests to make the wound on top of the fatty apron. The line of in cision, parallel to Poupart a ligament is infiltrated and the area anesthetized through the original bleb by advancing and retracting the needle point fanwise through the subcutaneous tissue. If the point of the needle is in continuous motion it is not necessary to test for vascular penetration by

THE 6 Location of incusion

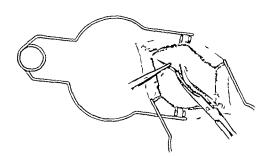

withdrawing the syringe. About 40 cubic centimeters of the anesthetic are generally used

An incision 2 to 3 inches (5 o to 7 5 cm ) long is made, depending on the thickness of the fatty layer The operation is more quickly and safely done through an adequate incision. The vein is

safely exposed by sharp dissection as traction is applied to the wound edges. Two layers of substantial superficial fascia are met and divided. In thin persons the deeper layer lies close to the vem. In the obese there is often considerable by under this fascia through which the vein mos-Retraction is by means of spring self retaining to tractors. The vein is usually met at about the level of its lowermost tributary. It is dissected free from its bed Exposure of the saphenous helb is then completed by separating adventitia and fascia from the year and dividing noward. The makes necessary a minimum of retraction (Fig. 7) In the majority of cases the superficul eutr nal pudendal artery crosses over the bulb. It serves as a landmark and may be divided if necesary. Often the artery passes next beneath the saphenous vein and occasionally it divides, sending small branches both over and under the veh-

The saphenous is freed up to its confluence wal the femoral and all tributaries are divided by tween ligatures of No o chromic catgut From three to five are usually encountered. The sa phenous is then ligated as high as possible will chromic No. o cateut. It is clamped distal to the and again 1 inch (15 cm) lower. The mteriesing vein is removed. The provinal stimp r secured with a C silk transfixion ligature distal to

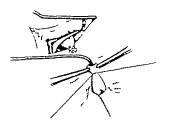

the first tie. The distal stump is grasped laterally with clamps (Fig 8) and the occluding clamp is re

I g 7. Fasca di ided upward along course of vein t. facilitate exposure of saphenous bulb and heation of tributanes

moved. A ligature of chromic No o catgut is reached with a half knot and a No 6 French ureteral catheter is introduced into the vein. It will usually enter 25 to 50 centimeters without difficulty. Occasionally the tip catches in a valve leaflet or tributary opening. Partial withdrawal and axial rotation of the catheter will usually enable it to slide past these obstacles but one must be careful not to push too hard as the vein wall is easily penetrated.

This procedure must be done quickly as the vein goes into spasm almost immediately. If the catheter becomes blocked and must be withdrawn reinsertion is almost impossible. When the cathe ter is at maximum insertion the half knot is tightened to prevent regurgitation, and wet saline sponges are packed about the vein opening to prevent any back flow into the tissues From 3 o to 10.0 cubic centimeters of 31/2 per cent sodium ricinoleate solution are injected, depending on the size of the varices and the depth of insertion of the catheter. Twenty five per cent of the sclerotic is first injected and the remainder is distributed uniformly along the course of the vein as the catheter is withdrawn. Occasionally one is unable to penetrate further than 20 centimeters or so even in the presence of a large saphenous vein. This is usually due to excessive tortuosity sclerosing solution can then be distributed distally by means of a gentle sweeping massage while it is being injected. A larger amount can be introduced with safety and more complete sclerosis obtained The knot is completed and reinforced with a C silk transfixion applied above the catgut tle. (If the vein is penetrated below this the

Ing 8. Technique of retrograde scleross. Half knot preents reflue.

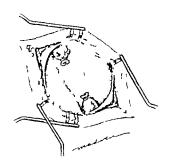

Fig. a. Operative site ready for closure. Thoroughly irrigated with saline

sclerosing solution will leak ) The wound is firity gated with saline (Fig. 9). Several interrupted line catgut sutures are placed in the superficial fascia and the skin is united with interrupted silk vertical mattress sutures.

While the assistant closes the wound the sur geon attends to the blowouts. The previously marked lines of incision 1 to 2 inches long are heavily infiltrated with 1 per cent procaine. This infiltration serves to separate superficial veins from the skin to which they closely adhere follow ing phlebitus or chronic dermatitus and edema of long standing The skin is cleanly incised and retracted with small rakes. Allis clamps necrotize the skin and should never be used to grasp skin edges. The vein is grasped freed and all avail able tributaries are clamped and divided. The T. shaped junction between vessel and perforator is sought. The vein is divided above and below between clamps to prevent escape of the sclerosing solution Should any escape the wound must be immediately flushed with saline. The vessels are tied with No oo plain catgut. Chromic catgut was found to be poorly absorbed by this thick ened poorly vascularized tissue particularly in the lower leg. The wound is closed loosely with two or three vertical mattress silk sutures

Ligation of the lesser suphenous is accomplished in a similar fashion (Fig. 10)

Dressing must be carefully done. The femoral inc. ion is entirely scaled with adhesive especially in women. The lower gauze dressings are held in place with diagonal rather than circumferential.

Fig. o. Variousities of lesser suphenous system. a, Posterior view. Large venous. Bannel marked where it lifes beneath fason. Y marks site of ligation. by Oblique view. Note enlarged greate suphenous coursing down modial aspect of knee. An excellent result was obtained in this case by ligating and scienous bells greater and lesser suphenous webs.

strips of adhesive to obviate tension in the event of swelling. If retrogrado sclerosis has been done the femoral and leg regions, groun to ankle, are pudded with combination dressings and the entire extremity bandaged firmly with two 4 inch Ace type bandages. If sclerosis has not been done, it is unnecessary to pad the leg but a 4 inch Ace type bandage is applied from toes to knew

Postoperative care Immediately the operative dressing is finished the patient is made to walk for 5 to 10 minutes. This distributes the accrosing solution more evenly enhancing its effect. Fudding' is prevented and danger from ven break down and its attendant difficulties is minimized. Following this, the patient goes to bed. There-after he is required to walk to to 15 minutes every a hours until he becomes completely ambulation. The outer bandages are removed after 6 hours and additional pedding is placed over any point which evens unduly irritated. The padding a discarded

after 3 to 5 days. The Ace bandages are replaced daily Most patients go home wrange Ace bandages to the kine only II the rance above the kinee are large, it may be necessary to hind the thigh for 2 to 3 weeks. When retrogued sclerosis is done the average hospital star a days if one, and 6 days if both sides are operated upon. If simple ligation has been done, the patient usually goes home the following day. The Ace bandages dor well fitting stocking.

are wom for from 8 to 12 weeks or until schools is complete, being removed only to bathe or when the patient is in bed. When scherols is complete the Ace bandages are discarded gradually. The legs will swell it thus is not done as vascular tractable to the Ace bandages as usual in the monthly and wear them until late aftermoon, when they are moved. If no swelling appears by bed time, to bandages are removed the next day in middite noon. Thus the boar of removal gradually becomes earlier until the patient goes wilked bandages entirely.

\*\*Particle removed the gradual of the patient goes wilked bandages entirely.\*\*

bandages entirely Postoperative injections: Where simple ligition has been done injections are beginn as soon at the wounds are well headed, i.e. ro to z days. Maitiple (three or four) punctures at one valit on the made as tolerated. I do not inject more than z cubic centimeters in one place or more than secuble centimeters at any one time.

cuble continueters at any one tune. If retrograde sciences has been done one should want at least a month before injecting any remaining veins. Frequently no further injection are necessar. It is my experience that many vein segments not initially thrombosed will become is without injection during the first 4 weeks after operation. The average patient, however seeds to injections to complete the obteration of the vances. I prefer to give an extra injection or two later than inject too much sciencing agent at the time of operation. Pratt originally used to to do cubic centimeters of solution. I use about our custer of this quantity.

## Comblications

I Postoperatus reactions A febrile response to retrograde scierous occurs depending on (s) the amount injected, (b) the size of the variety, set (c) whether both legs are done. On the scond and third days the temperature may reach 100.5 to 101 o degrees F Occasionally it is higher. This need occasion no alarm because better and more complete scierous occurs after increased feder response. However reaction higher than 101 degrees F is considered alboermal. Although I have noted no permanent ill effects, these patients

should be watched closely. I have seen several instances in which the temperature reached 105 degrees F on the third postoperative day and one instance in which it reached 107.4 degrees F All these complications were either in postphlebitic patients or in patients who showed signs of heightened vascular uritability. These patients were kept in bed with the legs elevated Papa verine 1/2 to 2 grains was given every 4 hours to lessen vascular spasm. Paravertebral novocam block was used in the more severe cases and extra fluids were administered Possibly these reactions could have been avoided with proper selection of cases for selerosis.

2 Femoral thrombosis I have observed no case of femoral thrombosus-a fact attributable to the exclusive use of local anesthena which makes

the patient immediately ambulatory

3 Hemorrhage No serious bleeding has been encountered following the use of silk transfixion of the saphenous stump Occasionally the femoral bandage becomes blood soaked during the period immediately after operation. This seepage of blood can always be controlled by pressure.

 Infection Avoidance of infection depends, I believe on (a) the use of a single puncture wound for anesthesia (b) delay of operation until dermatitis and other infections are cleared up (c) avoidance of injury to enlarged femoral lymph nodes during operation, (d) prevention of contam mation by proper dressing and the covering of the wound surface with sulfanilamide powder

5 Delayed healing of wounds Delayed healing of wounds frequently occurs without infection and only in the lower leg wounds. The lower the incision the more hable is healing to be slow Healing is frequently delayed about the ankle when incision has been made through edematous chronical ly inflamed skin. This difficulty is met with elevation warm socks, and suitable dressings

# Follow-up

The patients are seen at intervals after sclerosis is completed. The legs are inspected at the time the Ace bandages are discarded and again 3 months later After this I see them at intervals of 6 months. Any visible additional vances can then be injected. New vances occur and are not to be mistaken for recurrences. Occasionally recanali zation of certain channels occurs. This has been due usually to the presence of a blowout missed at the initial examination. Simple excision of the blowout followed by an injection or two remedies the situation SUMMARY

The origin of varicose veins is discussed and their anatomical types are enumerated together with the several types of bodily configuration in which varicose veins are most liable to occur Different methods of treatment and their indications are outlined. Injection of veins and operative technique are discussed in detail. Contra indications to the use of sclerosing solutions include (1) saphenous thrombophlebitis, (2) vasospastic disease of the lower extremities (3) obliterative peripheral vascular disease (4) abnormal reactivity to the test dose. Postoperative complications their avoidance and treatment are described. Analysis of cases and late results will be the subject of further communication when more time has elapsed.

# ADENOCARCINOMA CYLINDROMA TYPE OF THE PAROTID GLAND

# A Clinical and Pathologic Study of Twenty One Cases

FRANK W QUATTLEBAUM M D MALCOLM B DOCKERTY M D AND CHARLES W MAYO M D FACS Rochester Minnesota

A a previous study by two of us (Dockerty and Mayo 4) it was pointed out that there occasionally arose in the submaxillary sali vary gland a type of neoplasm variously known as cylindroma adenocarcinoma cylindroma type or basal cell carcinoma with hyaline The incidence of this tumor in a large series of submaxillary glandular neoplasms, was approximately 20 per cent. Throughout the literature as well as in our own series this tumor had been confused with the ordinary type of mixed sa livars glandular neoplasms. In this group of

cylindromas recurrence was extremely high and metastasis frequent with more than 50 per cent of patients succumbing from the effects of widespread dissemination of the disease. Chinically cylindromas could not be distinguished from the group of mixed tumors although pain was a contrast ingly frequent symptom. Surgically the intiltra tive tendencies observed by the surgeon made him sometimes question a fresh tissue diagnosis of However in this precellular mixed tumor vious communication distinctive microscopic fea-

tures of cylindroma were presented and it was shown that the surgical pathologist familiar with the cellular pattern could render a real service m advising radical operative procedures when such a neoplasm was encountered.

More recent experiences (5) demonstrated that adenocarcinomas of the cylindroma type affecting the tongue and the parotid gland were also dangerous from the standpoint of metastasis. Mulligan, in a recent review reported instances of 12 metastasizing mixed tumors, many of which had been primary in the parotid gland. Interest ingly enough most of the illustrations in his article duplicated the microscopic appearance of

respectively Methcal Corps, Army of the United States

The term cylindroms hence trusted in this paper appears
as an abbreviation for adenocarcinoms of the type cylindroms.

cylindroma in all major features. Since investgators still confuse mixed tumors with cybedromas and Bauer and Fox, on the basis of ; tumors, stated that cylindromas are genundy benign. It was thought advisable to conner a group of primary neoplasms of the paroud to ascertain whether or not cylindromas occurred there and, if so, whether or not their clinical behavior was that of their submaxillary come narts.

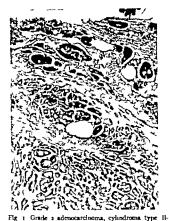

## MATERIALS AND METHODS

Material was available on 210 consecutive cases in which primary parotid neoplasms led been removed surgically at the Mayo Clinic be tween the vears 1028 and 1036 inclusive. This particular group of specimens was selected because a represented a series large enough to warrant conclusions as to the probable general moderce of parotid cylindromas and because it allowed ample time for a follow up in the cases occurring in the later years of the series.

Before any records were reviewed these 110 formalm-preserved tumors were carefully studied in gross detail special attention being paid to the features of size, color consistency presence or absence of encapsulation, amount of parotid ghadular tusue removed, presence of attached hunk nodes and so forth. Multiple blocks were cut look the turnors, the adjacent salivary gland, and regional lymph nodes when available. These blocks were placed in a 10 per cent solution of fresh formalin sectioned at a thickness of approvmately to microns and stained routinely with hematoxylin and cosin. Study of these sections brought to light 21 tumors which, although is many instances previously labeled atypical mind tumors, seemed to fulfill the criteria for a revied diagnosis of adenocarcinoma of the cylindrom type. The present report deals with the clinical and pathologic details of this group of 21 cases

# PATHOLOGIC DATA

Gross features In 19 cases the material vas such as to suggest that total or subtotal removal of the tumor had been performed and in a instance

lustrating resemblance to basal cell carcinoma. The honey combed plogs of malgrant cells are distinctive, as its absorbe hyaline stroms. The so-called capsule shown in the upper portion of the photomicrograph is cartenively in-vaded by malgrant cells (hematoxylin and cosin X44)

only a small biopsy specimen was available for study All of the tumors were unilateral In 4 cases the entire parotid gland was attached to large neoplasms of an infiltrative type and in 2 additional instances the presence of attached mangnant appearing cervical nodes indicated that fairly extensive operations had been performed In 7 of the remaining 17 cases the tumor appeared in the form of single or multiple grayish white encapsulated nodules. Rarely could the capsule be separated with ease from the underlying tumor tissue. Vonencapsulated examples always dem onstrated invasion of attached parotid glandular assue or the surrounding adipose connective tissue and portions of striated muscle which were occasionally removed with the operative specimen In I case an attached portion of the mandibular ramus was grossly invaded by neoplastic tissue

Microscopic features: The microscopic appear ance of these tumors differed in no essential respect from that detailed in a previous study (Figs. 1 to 6). The general architecture was that of islands and strands of small dark-staining cells with hyperchromatic nucles. Many of the units demonstrated central hone-combing with clear.

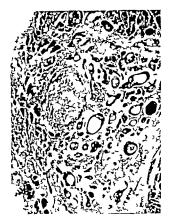

Fig 2 Grade 2 adenocarcinoma, cylindroma type il instrating again the basic architecture in addition to the phenomenon of perineural invasion by carcinoma cells (hematoxylin and coain X44)

spaces which in some instances were filled with hyaline substance, in others were occupied by globules of material which stained positively for mucus and in still others were empty stroma was in general hyaline. Infiltrative tend encies were pronounced the tumor capsule, the attached parotid glandular substances, the surrounding fat and so forth frequently demonstrat ing invading strands of tumor tissue running out from the parent growth Penneural involvement was observed in all 11 instances in which nerve fibers were found. Metaplasia to epithehum of a squamous type was noted in 2 tumors. All the other neoplasms were pure adenocarcinomas of the type cylindroma, 14 being of grade 2 and 7 of grade 1 malignancy according to the method of Broders. In 2 instances portions of the neoplasm demonstrated appearances somewhat typical of mixed tumor Previous experience had taught us that this group of 'intermediates ran the clinical course of cylindromas and accordingly they were included in the present series.

### CLINICAL DATA

Incidence The incidence of parotid adenocar cinomas of the cylindroma type was to per cent of the entire group Stein and Geschickter observed

Fig. 3. Grade 3 adenocarcinoma, cylindroma type, illustrating marked cellularity poor glandular formation and infiltration with splitting of the capsule. Enucleation in this case would have left behind multiple tumor secultings (bernatoxylin and coda: Xx6)

a 15 per cent incidence of this type. The corresponding figure for the submarillary salivary gland was 18.5 per cent according to Dockerty and Mayo (4)

Sex. Men and women were almost equally represented in this series, in keeping with the observation in the literature that salivary glandular neoplasms have no particular sex predilection.

Age The average age of the patients was 49 8 years with extremes of 32 years and 65 years.

Symptoms The commonest symptom related by the patients was the presence of a tumor with an incidence of roo per cent. The duration of the swelling varied from 6 months to 15 years with an average of about 7 years. It was thus impossible to judge on the beass of this symptom alone, the nature of the underlying pathologic process.

Half of the patients additionally complained of pain which was constant and localized in 2 in stances and intermittent and lanchasting in the remainder. Six patients had experienced extension of pain across the face, over the forehead or down into the neck, the character and distribution indicating irritation or actual invasion of a nerve by the tumor. In our experience pain was an unusual feature in connection with mixel sallwary.

Fig. 4. Grade 1 adenocarcinoma, cylindroma type is spate of good aciner formation and other evidence of cellular differentiation the infitrative propositions is evidence with the invasion of fat (hematraylia and cas-X41)

glandular neoplasms and its presence in patients suffering from primary perotid and submarihn swellings should make one alert to a possible or-

derlying adenocarcinoma of the cylindroma type On physical examination to tumors involved the right and 11 the left parotid gland. All times were unilateral. Location was generally described as being preauricular with certain tumors varying in occupying a high or a low position. The aver age estimated size was 4.5 centimeters with vanations from 1 to 7 centimeters. Whereas 10 of the tumors were somewhat movable, resembling mixed tumor in this regard, the remainder set described as being fixed a feature suggesting the presence of infiltration. As pointed out previously local fixation of the tumor is an important aign in distinguishing adenocarcinoma of the oil indroma type from mixed tumors of the salivary glands. Partial or complete paralysis of the facel nerve was present in 25 per cent of the cases at the time of first examination at the clinic. Whereas a several instances it is possible that this paralysi follows the performance of a previous operation we feel on the basis of pathologic studies that it # most often brought about through perineural invasion of the seventh nerve.

Fig. 5. Grade 2 adenocarcinoma, cylindroma type. This neoplasm was "recurrent" and illustrates extensive invasion of structed muscle (hematoxylln and cosin ×44)

At operation only 39 per cent of the tumors were invested by anything which could be described as being a capsule, the remainder demon strating evidence of infiltration. It was estimated that complete excision was accomplished in 50 per cent of the cases. However, several of the cases in which the surgeon made a note regarding residual tumor tissue were instances in which previous operation had been performed and the neoplasm was listed as a recurrence.

# TREATMENT AND RESULTS

Treatment consisting of wide local excision alone or combined with postoperative therapy using roentgen rays was employed in 15 cases. Complete parotidectomy was performed 4 times for large neoplasms 1 of which represented a recurrence following a previous 'local operative procedure. In the 2 remaining instances biopsy followed by roentgen therapy was the thera peutle regimen dictated by the presence of an ir removable tumor mass. Fourteen of the patients received their first treatment at the Mayo Clinic. In 7 cases treatment institute elsewhere was con tinued at the clinic because of neoplasms which had recurred.

Follow-up studies are available on 20 of these 21 patients and the detailed results are given in

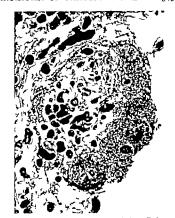

Fig 6 Grade 2 adenocarcinoma, of the cylindroma type, with the invasion of a lymph node (hematoxylin and cosin ×44)

Table I Although we have no necropsy data on the 10 patients who have died presumption that death was owing to the effects of carcinoma is af forded by roentgenograms positive for pulmonary metastasis in 5 of the group and of cervical nodal metastasis in 2 additional cases. The 5 patients who are living without any evidence of recurrence represent a disappointingly small group (25 per cent) The 2 deaths and the 2 recurrences in the group subjected to total parotidectomy make a poor showing for an operation of such magnitude. However these 4 patients were suffering from very large infiltrating neoplasms. Paralysis of the facial nerve was present in 25 per cent of the pa tients on their first admission. It developed in an additional 43 per cent at a time following opera tion, which indicated a causation based on infil tration by recurrent tumor in all except the 3 cases in which the nerve was purposely sacrificed in the operative attempt to eradicate large tumors.

### COMMENT

Although adenocarcinoma of the cylindroma type occurs in all locations which provide the tissue of origin for mixed tumors of the salivary glandular type it is our firm opinion that there is no justification for including the two types within the same category. Histogenetically mixed tu

mora arise from the epithelal cells of the salivary and lacrimal glands and also from mucous gland-ular elements of the lip tongue, pulate, larynx, and trachen. The tumors are well differentiated, often reproducing in fair detail the double layer ing of epithelium which characterizes the appear ance of a normal salivary duct. A cartilage-like stroma is typically encountered. In adenocard norma of the cylindroma type ducts lined by double layers of epithelai cells are lacking the appearance being that of dark-staining house combed epithelail plugs. This may indicate as

suggested by Bauer and Fox, a derivation from the basal basket, regenerative or "mvo-epithein" layers of the glands and ductor of origin. Curlaginous stromal changes are not occurred by hyalineation of the stroma is of frequent over

Clinically Tocation and duration are intures which in a given case are by no nean disnostic of 9 indromas as opposed to murel time. The clinical locidence of pain, however was go per cent in our group of cylindromas. In series of submanillary neopleams pain had as is either of 70 per cent as opposed to a sope red incidence as a symptom of maxed tumor & cordingly we feel that pain, especially of a shape radiating nature is of importance in differential clinical disposass. Of parallel significance wastefinding of fixation which in our expenses was noteworthy feature of cylindromas.

At surmoal exploration cylindromas were found to be infiltrative in more than half of the cases and rarely in these cases was the surgeon satisfied that he had completely eradicated the days. That his estimate was correct is attested by a recorence rate of 75 per cent about three times the incidence for recurrence of mixed tumors (1) The question is therefore raised whether or not more radical surgical measures should not be under taken for this more malignant cylindroma group To most surgeons the mere mention of paretdectomy calls up at once the specter of a patent with severe facial polsy. However, the analysis this series reveals that almost one third of the prtients had partial or complete paralysis of the homolateral facial nerve at the time of admissor and this incidence reached two-thirds at the find analysis. That this figure is three or four times a great as the corresponding one encountered amorg patients operated on for mixed tumor (1) kno strong support to our pathologic observation that permeural involvement by tumor tissue rather than surgical trauma had been the factor responsble for the paralysis.

Admittedly if paralysis, complete or more plete, of the facial nerve exists preoperatively a is due to the perineural invasion or pressure of the

If paralysis develops immediately after operation it is due to surgical interference with the nerve. This paralysis may be partial or complete. If it is partial it is usually due to tensoo of stretching of the nerve and slowly improves. If it complete rumediately the paralysis of the entire is likely to be surgical and permanent. In a small percentage of cases, bowever complete paralysis may become partial and m a much small.

number the patient may completely recover from

Paralysis developing a month or more after surgical resection can be safely attributed to in complete eradication of the pathologic process and continued extension by infiltrating involvement

Bailey has performed total parotidectomy for 7 parotid tumors with resultant palsy of the seventh nerve in 1 instance only demonstrating thereby that surgical 'interference with the nerve can at least occasionally be avoided 1. In the 4 cases in which total parotidectomy was done in the present series the facial nerve had to be sacrificed because of large infiltrating neoplasms. Subsequent recurrence in all 4 cases and death in 2 of them in dicated to us merely that the operation was too late rather than too little. It seems logical to assume that since resection of the gland although usually effective in the treatment of mixed tu more is followed in the cylindroma group by a 75 per cent incidence of recurrence, procedures at least approaching total parotidectomy should here be given a fair trial. We further feel that block dissection of cervical nodes on the in volved aide should be senously considered. In this regard as mentioned in the foregoing the surgical pathologist familiar with the appearance of these tumors in fresh frozen sections can render a real service to his surgical colleagues.

While therapy with roentgen rays did not in the present series have any pronounced effect in the prevention or control of recurrences we feel that its possible benefits should never be denied to any patient suffering from this serious form of cancer

## SUMMARY AND CONCLUSIONS

- I Ten per cent of a series of consecutive pri mary parotid neoplasms appeared to be adeno-
- All Wherter showed that the bonnan purotic gland consist of larger more feed and smaller deep lobe onesity distinct and readily segments. The feed and smaller deep lobe onesity distinct and readily segments. The two lobes if young the property of the sectian justachia substance. The two lobes if young they are labeled the state of the property of the feed of the property of the feed of the property of the feed of the f

carcinomas of the type cylindroma so classified because of a distinctive microscopic pattern

- 2 This group of 21 cases was characterized clinically by the presence of sharp radiating pain and local fixation of tumor in 40 per cent features unusual in connection with other primary neoplasms of this location. Partial or complete pa ralysis of the facial nerve was also a contrastingly common finding
- 3 Surgically the tumors were generally more infiltrative than encapsulated and application of the principle of 'wide local excision' prevented recurrences in 5 of 21 cases.
- 4. Pathologically the appearance of dark staining epithelial islands and strands with cen tral honeycombing in a hyaline stroma was diag nostic. Epithelial mucus was sometimes present Infiltrative tendencies were pronounced with a special predilection for invasion of nerve sheaths.
- 5 Eight of the 20 traced patients succumbed within 5 years to the effects of metastasis, 5 with evidence of pulmonary spread. Two died more than 5 years after operation. Four of the remaining to are suffering from inoperable (?) recurrences
- 6 Solid tumors of the parotid gland should be assumed to be malignant until proved otherwise.
- 7 It is suggested that more radical surgical procedures will have to be done in order to obtain better results in the treatment of this form of neoplasm

### A CLINICAL STUDY OF EARLY POSTOPERATIVE AMBUI ATION IN GYNECOLOGY

PAUL F STEINHART M D Les Angeles, California

ITH surgical e helency at its present level, we should not be satisfied merely with recovery from a surgical operation but we should know as Matas once stated how the patient has recovered, to what extent she has been restored to her anatomical and functional integrity to what extent she has been cured and made fit to return to her normal life and occupation how long it has taken her fully to recover after the operation and what are the end-results.

There is no excuse for leaving a single stone unitarities to suffering shorten the convalencence, and eliminate the economic waste incident to surgery on human beings (20) and, if early postoperative ambiliation is an added means toward this end, then its use should be more widely adouted.

A comparison of the relative ments of early ambulation with those of late ambulation will be made in the following report. This presentation may in effect, along with similar preceding reports (17 az 23 25 27) remove prejudice and add to the surgeon's postoperative therapeutic armamentarium. Of course, there are limitations and although this sense was consecutively treated by early ambulation, the surgeon's judgment should individualize each case. However the results demonstrate that fear of early ambulation is in the majority of cases, unwarranted.

#### PRESENTATION OF DATA

Fifty four consecutive cases are herewith ducused. The first 17 patients were maintained on the conservative regumen of late ambulation the following 37 patients received early postoperative ambulation. No attempt was made to collect additional cases of patients treated by the old regumen because it was desired to maintain the factor of the operator constant. Because of this fact no attempt will be made to quote percent ages only a relative compension will be made.

Since the original compilation of this report, several additional patients were also treated by early postoperative ambulation with apparently

From the Department of Obstetrics and Graccology University of Nebraska, College of Medicine, University Hospital, Osaha, Nebraska.

similar results, but are not herewith included because of insufficient follow-up

All patients were charity cases, from near sections of the State of Nebraska. All patient received adequate preoperative care. Patient with low blood counts and hemogloim value aceived adequate transfusions.

The technique of operation was constant is both series.

Of the patients ambulated early  $\gamma$  had Pionenstiel incisions, the remainder had make medians. All of the patients ambulated his had midding incurous.

In all total abdommal hysterectomies, 5 press of sulfathiazole powder or crystals was introduced into the abdomen prophylactically. In other cases, only in the presence of old infection was saifa sulfa powder or crystals used.

Abdominal closure was made by lavest, the pentoneum was closed by a continuous stick of No. 0 or No. 1 plain catgot the fasca was done by a continuous stitch of No. 0 or No. 1 thrust catgot from each angle to the middle of the cision the skin was closed with fine dermal instructed vertical mattress satures. No tensor satures were used (except in the case of spaics because of obesity—weight 245 pound—on what an incidental incisional ventral hemiocraphy to performed).

Spinal anesthesia was used in the majorty of cases cyclopropane and ether were used so when spinal anesthesia was refused. In a vojfew cases, the spinal anesthesia was refused. In a vojfew cases, the spinal anesthesia was implemented with cyclopropane and ether near the dose of the operation. One elderily patient aged 74 years, are operated upon under local anesthesia of 1 prominovocaus for the removal of a very large oration cyst a multillocular serious cystademost.

There were no postoperative dietary returning in either senes. Diet was taken at tolentel leguids, soft or regular. Intravenous fulls were rarely administered immediately postoperative and this treatment was carried out only if operation was extensive. Fluids were sufficient taken orally.

A retention eatheter attached to a bottle six used after all plastic operations and ragual hysterectomies. In the patients ambulated early

the catheter was kept in for the first 24 hours (except for 2 cases, one a vaginal hysterectom) performed on an obese patient weighing 217 pounds and the other a urethroplasty in which the catheter was kept in for 48 hours). In the patients ambulated late the retention catheter was used for 72 to 96 hours. In 3 total abdominal hysterectomies (2 in the early ambulated series and 1 in the late ambulated series) because some difficulty was encountered in the dissection of the bladder from the cervu a retention catheter attached to a bottle was used for the first 24 hours. In all other cases patients were cathetenized only when necessary

A study of the patients treated revealed the following salient features

The age range of the patients treated by early ambulation was from 15 to 74 years of those treated by late ambulation 30 to 70 years. The mean age of those ambulated early was 41 2 years of those ambulated late 52 1 years. The weight range of the patients ambulated early was 110 to 225 pounds of the patients ambulated late

\*Unilateral or bilateral sulphage-cophorectomy or incidental appendentomy were performed on some of these patients.

112 to 230 pounds. The nutritional status of the patients in both series was approximately the same.

In the early ambulation series, there were 2 patients with hypertensive heart disease 1 with rheumatic heart disease 2 with positive serology (Mazzini) and 1 with chronic bronchitis. In the late ambulation series there were 3 patients with hypertensive heart disease and 2 with diabetes mellitims.

Wound healing was not affected by the positive serology or the diabetes mellitus in either series.

The surgery performed on the patients ambulated early included 5 total abdominal hysterectomies 6 subtotal hysterectomies 13 laparot omies for surgery other than hysterectomy 3 vaginal hysterectomies 7 plastic operations 2 combined abdominal and plastic operations 1 cesarian section (this case is included because of the abdominal surgery entailed) For the pathology associated with these cases see Table I

The surgery performed on the patients ambulated late included 3 total abdominal hysterectomies 1 laparot omy for surgery other than hysterectomy 4 vagnal hysterectomes 5 plastic operations. For the pathology associated with these cases see Table II.

The patients who were ambulated early wore tight abdominal binders and, in the majority of instances, got up in a chair on the first postopera

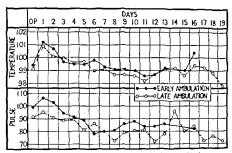

Fig A composite graph of the temperatures and pulse rates of both sensa.

tive day with bathroom privileges. A few be cause of hesitation and fear dangled on the first day (8 out of 37 patients). All patients were up and about on the second day. Two patients who had undergone vaginal hysterectomies and 1 who had undergone a urethroplasty were ambulated on the second day because a retention catheter was used for the first 48 hours. Early ambulation was not insisted on but was encouraged. This series includes 4 patients, s of whom ambulated themselves on the third day 2 of whom ambulated themselves on the fourth day. The majority of nationts who were ambulated late got up in a chair on the seventh or eighth day I patient got up on the sixth day I on the tenth day and I on the twelfth day

A composite graph of the temperatures and pulse rates of both series (Fig r) such as was presented by Powers in his report, shows relatively little significant changes due to early ambulation. Like that of Powers, these were plotted by averaging the highest levels recorded for every patient on each day and thus represent maximal elevations during the convolucions therefore.

Postoperative invalidation, both psychical and physical, was markedly reduced in the patients who were ambulated early. There was less apprehension on the part of the patients and the lamly, as to the patients condition and prognous. There was a notable decrease of the usual postoperative complaints on the part of the patient. Nursing care requirements were markedly reduced.

The necessity for catheterization of patients with abdominal surgery occurred for the most

part on the operative day and the number of teents requiring catheterisation was relatively its same in both series. Of the patients ambeted early 10 of the 35 abdominal cases required alterization and this on the operative day. Or patient only required a second catheterizates as the first postoperative day. Of those smbollate, 3 of the 8 abdominal patients report active terrization and this was necessary or in operative day only

All the patients on whom plastic operations and vaginal hysterectomies were done, whether atbulated early or late, showed the same relative frequency of catheterization following removal of the retention on theter Of the patients ambulated early 2 out of 12 required catheterization once; the patients ambulated late, r out of 9 required catheterization once. The early ambulated patients, however emptied their bladders port completely suggesting that in these types operation there was an earlier return of hinder tonicity with early ambulation Although a studof residual urine was not carned out in all case due to a shortage of nurses, the findings in the cases in which this study was done seemed to confirm this fact. A more complete study of all the cases, made by averaging the lowest quantities of urine voided, the highest quantities voided and the frequency of voiding for the first 3 days lolowing removal of the retention catheter revoled that the patients who were ambulated can't vonded larger quantities and less frequently (Table III)

In both series there were a few patients sho were able to move their bowels without the ail of

#### STEINHART enema however the incidence was greater ong those who were ambulated early (14 of the

patients ambulated early compared with 2 of 17 patients ambulated late)

There were no cases of abdominal distention in e patients who were ambulated early and only x se of moderate distention in the patients who

The requirements of sedation during the opera we day were comparatively the same in both After early ambulation seciation was enes.

The number of hospital days here reported is arely required not necessarily a true indication of the hospital days required for convalescence. Since patients came from many sections of the state and in many cases were required to travel great distances, discharge from the hospital was made according to the convenience of the patient and not necessarily at the time when the patient was physically able. Some patients stayed as long as 2 to 5 days beyond the time of discharge Because this factor was constant in both series, the relative number of hospital days saved is still quite evident. The average number of hospital days required by the patients who were ambulated early was 8.72 days as compared with 13 94 days required by the pa tients who were ambulated late. Early ambulation therefore, saved an average of 5 22 hospital days per case. A comparison of the average number of hospital days required according to the type of operation performed is given in Tables IV and V • ĸ

The patients ambulated early developed the following postoperative complications plained fever 2 cases acute bronchitis, 1 case phiebitus, I case hematoms in incision I case.

Unexplained fever occurred during the post operative course of 2 patients, one upon whom a vaginal hysterectomy had been performed and the other a plastic operation Physical examina tion and laboratory findings were negative in both CB 505.

Acute bronchitts occurred in a patient weighing 217 pounds, with known chronic bronchitis, on whom a vaginal hysterectomy was performed. The patient had a predisposing focus of infection and it is possible to conceive that early ambula tion in this very obese patient prevented the

possibility of bronchopneumonia. Phlebitis occurred in a patient on whom a urethroplasty was performed. Early ambulation in this patient was evidently insufficient prophy laxis against this attack of phlebitis. It may be noted that this patient had a milk leg in the opposite leg 20 years ago following a normal delivery

	TABLE	111	
	Mary Control of the last of th	Highest quan-	Frequency
	Lowest qua tity	tity washed	day
Patients	October	3 (100 c.c.)	
Ambulated early	\$ ( 50 cc.)	(900 )	<u></u>
Ambulated late	4 ( 50 CE)	i occurr	d in a Pa

A hematoma in an incision occurred in a pa tient who had a Gilliam suspension. The hema toma was at the level where the round ligaments were anchored to the fascia and evidenced itself by a I inch gape of the incision on the sixth post operative day While this hematoma may be attributed to early ambulation it is concervable that a small unrecognized bleeder may have been produced at the time of operation in one of the perforations of the fascia and rech muscles through which the round ligaments were drawn.

The patients ambulated late developed only I poetoperative complication I case of unexplained lever Unexplained fever occurred after operation in a patient who had undergone a vaginal hysterectomy Physical examination and laboratory

findings were negative.

on these patients revealed that the convalescent period at home was much less for those patients who were ambulated early Of the patients ambulated early 8 were able to resume their normal activities immediately after leaving the hospital of those who were ambulated late only I was able to do so The average con valescent period at home required by the patients who were ambulated early was 3 87 weeks, com pared with 6 5 weeks required by those who were ambulated late. The average total convalescent period required by those who were ambulated early was therefore 3,3 weeks less than that required by those ambulated late. The duration of convalescence according to type of operation is shown in Tables IV and V

A follow up of both series, over a period of 6 to 8 months, has revealed no disruption of wounds, no incisional ventral hernins, no recur rent cystorectoceles, no prolapse of the vault of the vagina following vaginal hysterectomies.

DISCUSSION The above data reveal certain obvious clinical advantages in early postoperative ambulation. A study of the etrology and pathology of post operative pneumonia atelectasis, embolism in farcts, phlebothrombosis, etc. indicates that enrly ambulation also offers advantages in the prophylaxis of these conditions.

With the patient on her back following surgery the stage is set for many hours of recumbency with

shallow breathing (4, 25) There us pooling of the tracheobroachia sceretions in the finer ramifications of the broachial tree and very often a discincination to cough due to pain. This, in association with the limitation of the respiratory excursions, allows for an obstruction in the distal broachioles. The free dramage by which the lung is kept in an aseptic condition is interfered with the air distal to the obstruction is absorbed the corresponding lobules collapse and in the occluded area, with a predisposing infection, a mild pneumonia may develop

The increased long expansion afforded by the exercise of early ambulation would no doubt aid in the prevention of the pooling and stasts of the tracheobronchial secretions, and hence early ambulation should be definite prophylaxis against such pulmonary complications.

The metabolism (7) and muscle tone of the recumbent patient are low. There is a decrease in the volume of flow in all the versels of the body. The venous pressure is low and the caliber of the

veins, especially in the abdomen, pelvis, and lesis much smaller than when sitting up. Only when the patient is sitting or standing are these vers constantly dilated. Frykholm suggested that collapsed veins may have endothelial damp. predisposing to later thrombous. Vens, which are compressed and empty due to pressure of the legs against the bed as suggested by Dock, and easily suffer endothelial damage and begin to thrombose while nearly empty. Dock futher pointed out that phiebothromboris may begin in the venules of the muscles and subcutis, or is the pelvic venous plexuses where complete stars is possible. The formation of large clots propagated far along the system is made possible by prolonged recumbency The dislocument of data with the formation of emboh is effected she after this prolonged recumbency there is a saide ruse of venous presente such as is produced by getting out of bed or straining on a bed pan-

Pulmonary embolism has always been a but bear of surgery especially in gynecology and

obstitutes. It may occur suddenly in uncompile cated cases of patients who have progressed satisfactorily. The patient is allowed up out of bed for the first time on the seventh day or later and like a bolt out of the blue, a fatal embolism occurs. Fortunately this accident is not very frequent however when it does occur it is grim tracedy.

Since muscular activity increases the venous circulation of the lower extremities, walking would prevent stass in the venules of the muscles also since sitting or standing increases the caliber of the pelvic venus, stasis in the pelvic vessels associated with recumbency is thus removed. The prophylaus afforded by early postoperative ambulation against such postoperative accidents.

should be quite apparent

Early postoperative ambulation in plastic operations and vaginal hysterectomies causes no additional pain or discomfort. Patients who were ambulated early felt much more comfortable and invalidism was greatly decreased. Pain on sitting in a chair is avoided by the use of an inflated rubber cushion ring.

There may be some pain in the incusional area of abdominal operations on the initial attempt to arise, but this quickly subsides. The patients then feel more comfortable and from then on they have very few if any complaints about pain Patients who had previous laparotomies in which they had been treated by the conservative regimen of late ambulation themselves volunteered the information that with early ambulation they had less discomfort and very little pain

It has already been stated that a follow up of the patients treated by early postoperative am bulation in this report has revealed no wound disruptions, no incisional ventral hermas, no recurrent cystorectoiceles, no prolapse of the vault of the vagina following vaginal hysterectomies and a study of the etology of these conditions suggests up reason why early postoperative ambulation should result in a greater incidence of these conditions.

The breakdown of plastic operations or the prolapse of the vault of the vagina following vaginal hysterectomies may be entirely attributed to poor surgery or poor tissue, fascal etc. or both. Recurrent cystoceles or prolapse of the vault of the vagina following vaginal hysterectomies are seen frequently in patients who were ambulated late. Anatomically it is not conceivable that walking or atting produces any significant stress or strain on the fascal supports of the bladder or rectum or the uterosceral and round ligaments which are used to support the vault of the vagina.

following vaginal hysterectomies. A cough or a sneze in bed would cause more strain by the increased intra abdominal pressure thereby produced than would walking or aiting

R A Cutting wisely stated that if unusual strains were a frequent cause of wound rupture the condition might well be expected to occur with a far greater degree of frequency than it does, because even though unusual strain be construed rather harrowly such strains occur far more frequently than wound rupture.

Brettauer in 1899 was the first to describe wound disruption in the American literature, with a report of 3 cases. Several large series (3 8 10 II IZ 21 24 28 29) have since then been reported. One is impressed with the variety of opinions as to etiology. There are many prediaposing and precipitating factors suggested as being responsible for wound disruption.

The salient predisposing causes as evidenced by the many reports in the literature include the following obesity or asthenia (28) malnutrition (28) hypoproteinemia (13 15 26 28 30), avita minosis (13 28) low ascorbic acid level (13 28 32) dehydration (28) diabetes mellitus and similar disturbances of sugar metabolism (32) malignancy (28) especially if previous radiation has been given and presence of acute or chronic pelvic inflammation (28)

The technique of wound closure is of obvious importance and various factors have been emphastized Many have stressed in the technique of wound closure the significance with respect to the careless hemostasis (14 16) too tight suture of the fascia (6) the graping of large masses of tissue in ligatures (18) excessive use of catgut (1)

The salient precipitating factors, as evidenced by the many studies of evisceration are all conditions which increase the intra abdominal pressure (11 12 24 28 29) These include abdominal distention, with severe coupling or persistent emeals, hiccoughing etc.

The etiology (6 18, 19) of postopernitive in cisional ventral herma is similar to that of wound disruption. Here, too poor operative technique and postoperative complications, such as abdomnal distention associated with vomiting coughing and hiccoughing are stressed

Considering all these factors, it is difficult to conceive that wound disruption or incisonal herma should occur more frequently with early postoperative ambulation than those treated by late ambulation. Predisposing causes of wound disruption or incisional ventral herma such as malnutrition. hypoproteinemia avitaminosis

scurvy (low asorbic acid level) dehydration and so in should be eliminated by good preoperative care, a recognized necessity for all surgery. The importance of good operative technique in abdominal closure is taken for granted whether the patient is ambulated early or late. Should abdominal distention occur as a postoperative complication the surgeon's judgment should of necessity forbid the continuation of early post operative ambulation, if already instituted, and appropriate measures should be taken to treat the cause of the distention.

It is interesting to note that in many reports in the literature, the incidence of wound disruption appears to be approximately the same as the incidence of fatal pulmonary embolism following surgery In a study of wound disruption Schmitz and Beaton found an incidence of 0.18 per cent. Glenn and Moore (10) o 66 per cent Norms, o 5 per cent. Singleton and Blocker 0.67 per cent. Barker et al. in a statistical study of pulmonary embolium, found that the incidence of fatal pulmonary emboli, associated with major gynecological surgery ranged from 0 53 to 0.73 per cent. The mortality rate of wound disruption, how ever appears to be at least 50 per cent less than that of pulmonary embolism. Bowen found that the mortality rate of wound disruption ranged from 16 to 75 per cent. The average reported mortality rate of wound disruption according to Schmitz and Beaton is 34.8 per cent. It seems logical, therefore, to employ early postoperative ambulation as prophylaxis against pulmonary emboham in spite of fear of wound disruption. which is unwarranted as has been indicated.

#### YEARUS

Fifty four consecutive cases are reported the first 17 cases were maintained on the conservative regimen of late ambulation, the following 37 cases in the group received early postoperative ambulation.

- The temperature and pulse rates showed relatively little significant change due to early ambulation.
- Postoperative invalidism, both psychical and physical, was markedly reduced in those patients ambulated early
- 3 The nursing care requirements were mark edly reduced.
- 4. No significant difference was noted in the requirements of postoperative cathetensation in abdomunal cases. In plastic operations and vaginal hysterectomies, however an earlier return of bladder tonicity was suggestive in those patients ambulated early

- 5 Those patients ambulated early were relatively more able to move their bowels without the and of an enema.
- 6 Sedation was rarely required after patients were ambulated early
- 7 The average number of hospital days required by the patients ambulated early wn δη days, by those ambulated late 13.94 days, the saving an average of 5.22 hospital days per ptient for those who were ambulated early
- 8. The average convalencent period at loss required by the patients ambulated early was if weeks by those ambulated late 65 weeks. The average total convalencent period required those who were ambulated early was 3.3 well those who were ambulated early was 3.3 well less than that required by those ambulated let.
- 9. A study of the etiology and pathology of postoperative pneumonia, atelectass, philothrombosis, embolarm, and infarcts indicate the early postoperative ambulation also offers at vantages in prophylaxis.
- To Pain and discomfort as a result of each postoperative ambulation were not in evidence this series. In fact, the patients who were and lated early had less pain and discomfort the those who were ambulated late.
- 17 Early postoperative ambulation in pairs operations and vaginal hysterectonies shock is sult in no greater incidence of recurrent cytodic prohapse of the vaginal walls following varieties. Anatomically there is no educate of added significant stress on the fastic alignmentors supports from early ambulation.
- 12 A study of wound disruption and incisonal hernia suggests that early postopeative ambettion should not in itself result in a greate is cidence of wound disruption and incidenal herni providing, of courte, the patient has received and preoperative care and the usual good opening technique.
- 13 Follow-up in this series revealed no wood disruptions, no incisonal hernias, no recursicystorectoceles, and no prolapse of the ragmivaults following vaginal hystrectomes.

#### CONCLUSIONS

Early postoperative ambulation in graceing reduces the usual postoperative irralidism, see psychically and physically and results in sea rapid convalencence. Gestrointestinal and sea det toolety may be increased. Very little, day redation in required after early ambulaton instituted. Nursing care is markedly reduced instituted. Nursing care is markedly reduced

There is a definite advantage in carly amountion as prophylaxis against postoperative post-

monia, atelectasis, phlebothrombosis embolism and infarcts. Early postoperative ambulation per se should in no way increase the incidence of wound disruption, postoperative incisional hernia, recurrent cystorectoceles following plastic operation or prolapse of the vaginal vault following varinal hysterectomies.

#### IPSILATERAL SPASTIC RECTUS ABDOMINIS IN A PURELY THORACIC WOUND

BSERVATIONS on wounds of the thorax within the first few hours after injury have yielded some inter esting side lights on these dancerous wounds. In one action resulting in 250 deaths on the battlefield 60 deaths or approximately 25 per cent were due to wounds involving mamly the chest. Death from chest wounds on the battlefield or at the forward dressing station occurs most frequently due to massive hemor rhage from injuries to the heart the aorta the vena cava the hilar vessels or even to the subclavian vessels running over the apex of the lung. If the wounded man survives the threat of immediate hemorrhage and can be transported to an evacuation hospital his chances for survival are greatly in creased but even here death from exsangua nation may still occur although in decreasing numbers as pooled universal group O blood

and massive transfusions are made as readly available as plasma

A second cause of early death is a tenion pneumothorax incident to a laceration of the lung or of a bronchus, which may open as the lung relaxes in expiration. The obvious dysones, the immobile but distended here thorax the resonance on percussion and absence of breath sounds, give clearest evidence of the need for prompt withdrawn of air but not infrequently the need for the continuous escape of air is unrecognized and death from resouratory and circulatory fallow occurs A patient who has had one aspiration for a tension pneumothorax with removal of apparently sufficient air to correct the mediastinal displacement must be under careful and repeated observation for the next 48 hours lest a recurrence of the pneumothorax be overlooked. The introduction of a needle or of a catheter into the chest for the continuous escape of air should not be approached with timidity even by surgeous inexperienced in thoracic work. If an under water seal or a flutter valve is also provided, one need have no hesitancy in producing such a temporary opening into the thoracs **cavity** 

A fascmating but poorly understood early observation in connection with wounds limited to the chest has been an accompanying abdominal wall rigidity usually unlateral, or casionally bilateral and often associated wit subcostal tenderness on palpation and recussion strongly suggesting an intra-abdominal injury. There is also obsence or marked reduced amplitude of excursion of the abdominal wall during respiration suggesting is immobile or spassic diaphragm or even as

underlying peritonitis Frequently these signs are present only in the early hours after in jury, they disappear spontaneously some times within 18 hours and they rarely persist nore than 48 to 72 hours In the first few hours after injury they may be so pronounced that one might easily be tempted to perform an abdominal exploration for a

Occasionally in association with through runtured viscus and through wounds of the lower right chest, the nght dlaphragm and dome of the liver may sustain an injury which is quite unsuspected before its disclosure at operation or at autopsy with a resulting rigidity of the abdominal wall and tenderness of the entire ibdomen due to the irritating effect of bile and blood in the perstoneal cavity

It is not uncommon of course, to find such abdominal spasticity and subcostal tender ness on the same side as a lower lobe pneu monia attributable to involvement of the imphragmatic pleura in the inflammatory process In the cases under discussion there was no injury to the diaphragm and no in flammation except that incident to blood in the pleural space. In one case autopsy served to illustrate the frequently observed phenomenon of a spastic abdomen associated ath injuries entirely limited to the chest

A number of nonfatal cases could be cited illustrating the effect upon the abdominal wall of purely thoracic injuries Conversely similar phenomena involving the uninjured chest, consecutive to wounds of the abdomen have also been ovserved What operator has not noted following a McBurney incision or a right rectus incision or a wound of the flank, a definite lag in respiration a limi tation in the excursions of the chest and diminished breath sounds on the side of the wound even with no evidence of bronchial obstruction or atelectasis to explain it?

In one instructive instance three observers independently concluded that a private with a large left flank wound draining feces through a tangential laceration of the colon had a left subphrenic abscess due to high fever diminished respirations faint breath sounds dullness suggesting a high diaphragm and tenderness on heavy percussion of the left lower chest When no pus was found on aspiration at several points the wound itself was widely opened, and a large piece of shrapnel and sequestrated bone were removed from a lumbar abscess followed by complete disappearance of all chest signs

A connecting link between the two serous lined cavities is the sympathetic chain but the mechanism whereby it acts is unknown due to our limited knowledge of the sym pathetic pathways and the direction of their impulses. The intercostal nerves may be part of a reflex arc capable of mediating pain ful stumuli from the site of injury and affect ing the abdominal wall innervated by them A third possible explanation lies in the irritating effect of free blood in the pleural space upon the panetal and diaphragmatic pleura and upon structures which are un The early accustomed to its presence disappearance of this effect may be the result of dilution of the blood through pleural weeping Whatever its explanation this highly interesting reciprocal relationship between the two major serous lined cavities of the body and how it is mediated should yield

to carefully planned experimentation Surgeons generally should be aware that in the presence of a chest wound, a spastic tender abdomen does not necessarily require a laparotomy and if clinical and x ray studies definitely disclose that the missile in its line of flight did not traverse the abdomen or its parietes one may safely disregard the abdom inal signs.

#### THE SURGEON'S LIBRARY

#### REVIEWS OF NEW BOOKS

THE book by Clement A. Smith. The Physiology of the Newborn Infant is a monograph which deserves more than passing notice. Pediatriclass and obstetricians particularly will find it useful. Lack of a source book of information on this subject has long been felt. New clinical observations and scientific research during the last few years have added much to knowledge in this field and have made all previous accounts of neonetal physiology obsolete. The present text assembles these data

The text concerns itself with the period of the newborn and its transition from fetal life. The subjects of respiration, circulation, blood, metabolism direction, assimilation renal physiology endocrinology and immunology are treated. Thus it is culte a complete treatise of neonatal physiology with the exception of the nervous system and sense organs. The author states that the absence of the section devoted to the pervous system is not an oversight most of the available knowledge upon that subject, he points out, is limited to the fetus or is anatomical in nature or considers the newborn period only briefly in relationship to general neuromuscular development. It is indeed true that physiology of the nervous system at the time of birth and during the first few months of life is a terra incornita

The author himself has contributed acientifically to a number of the subjects dealt with in his book. Thus he writes with great insight. The reviewer was especially pleased with the chapters on respira-tion and circulation. However each succeeding chapter of the book is so full of new and important information that it seems more important than the preceding one None is dull each makes good read-

ing One of the outstanding features of Professor Smith's monograph is the presentation at the conclusion of each chapter of a clinical summary in which the scientific data are discussed briefly from the standpoint of practical medicine. It is these summaries which make the book so useful to the clinical reader. Another interesting summary is found in a table printed on the back imide cover This is a table of normal values at birth and on suc creding days thereafter. It serves as a ready and handy reference synopsis Excellent bibliographics appear at the end of each chapter

The Physiol gy of the Newborn Infant is very at tractively printed and bound. It is not a large book. The text including the index occupies only 312

pages. Great credit is due the author for erttor into such small volume so very much metal and Interesting material WILLIAM F WHITE

THE third edition of Fractures of the Jees by by and Cartis<sup>2</sup>, will be received with proper ap-preciation by all who have to deal with manifofacial surgery The writing is clear and concre, and the subject matter carries the authority havel as vests of personal experience. The authors describe their own successful methods and also those of metemporanes in a generous manner. The character of the text remains the same, however various new techniques and methods of firstion have been added

We would particularly draw attention to the sections on roentgenographic technique and detay management. These two important adjuncts to the successful treatment of law fractures cannot be to highly commended. Proper attention to these precepts will facilitate reduction of the fracture and recovery of the patient.

This compact book is well and profusely illutrated and it is a pleasure to suggest that every dentist, maxillofacial and general surgeon work profit by adding it to his library to read, study and

have available for ready reference. FREDERICE W MEDICINE

THE Primer of Electrocardiography by George Burch, M.D., and Travis Winson M.D. deorfbes in detail the fundamentals of electrocardio raphy In the strict sense the title is somewhat misleading for the book goes into more detail this the word primer' would lead one to believe. On the other hand, the authors probably felt that ties was apropos inasmuch as only the basic considerations of this diagnostic procedure were correct.
Through the liberal use of diagrams, each post is adequately exemplified. The theories of electrocardiography precardial leads, and discuss of the beart beat are well covered. The chapter on the elinical significance of the various components of the electrocardiogram is well written and will be a definite value to the beginner It will also serve as a handy reference to those who are more thoroughly versed in electrocardiography as it contains many details which cannot be found in books streams interpretation. Although no photographs of actual electrocardiograms are included the important

A PRINTER OF MELTICOCKEDIMENT BY Group Ranch, MD ACF and Traves Dissort MD Philadelphia Les & Frieger and TACF and Traves Dissort MD Philadelphia Les & Frieger and Tack Theory and

changes occurring in va yous types of heart abnor malities are adequately lemonstrated When used in conjunction with a manual stressing interpreta tion it should prove helpful in the study of electrocardiography

"HE second edition of a very clear and practical L book on The Intercritebral Disci by Bradford and spuring brings up to date our knowledge of this appearing names up to date out amornings of the clinical nuncer and places special emphasis on the cument dies Growth and mechanical factors are discussed in the first chapter with emphasis on the great antenor hydraulic compressive force placed upon the nucleus pulposus of the fourth and fifth lumbar dies in forward lifting strain Pathology associated with age change is comidered an important factor in disc herniation although sclerosis narrowing and vertebral hypertrophic changes are not commonly related to nucleus pulposus hermation

The clinical study of patients with "low back and catic pain" is very well presented except that there s continued confusion in reference to pain or along the course of the great sciatic nerve and lack of clear definition of symptoms and signs of single nerve root distribution. It is regret table that these authors who have been leaders in emphasis of neurologic diagnosis and unnecessary use of the spanogram should be unable to present any consistent dermatome pattern in the lower ex tremity and continue to use the somewhat un authoritative Tilney and Riley for illustrations of authoritative timey and rency for mustaction of dermatome patterns. These charts were taken from Dejerine (1914) without any very evident original work to support them, and certainly are outdated by the more authoritative work of Foerster (1933) The irregularity of the areas of hypesthesis in clini cal case illustrated in this book denotes inaccuracy of technique in plotting these areas Also there are conflicting statements about the occurrence of sensory loss in association with single nerve root in volvement the authors tending to adhere to Foer ster's dictum that this does not occur but citing a high percentage (75 per cent) of detectable hypes thesia in proved herniated nucleus pulposus cases with admitted single nerve root involvement. Better technique is needed on this subject as others are able to outline consistent diagnostic areas of derma tome hypalgesia from unquestionable single nerve

The roentgenological presentation calls attention to the u ual lack of diagnostic findings of herniation root loss. of the nucleus pulposus except by myelography or spinogram. The authors very properly reserve the use of the spinogram to atypical or doubtful cases in which localization cannot be made by history and betrologic signs calling attention to the possible complications and uncertainties of intraspinal

OURSE INCHES

THEFT THE ALDES, WITH SPICIAL REPT WE TO REPTE TO THE APPEND TO THE APPENDING AND THE APPENDING TO foreign media

Distinction is made in the application of manipu lation therapy it often being beneficial in earl) cases with predominant midline low back pain but liable to do harm in longer continued cases with entirely lateralized nerve root pain indicative of unreducible increased herve root pain indicative of uniconcine nucleus herniation. These latter cases may improve under long continued conservative rest or orthopedic treatment due to subsidence of acute swelling or to a destroyed insensitive nerve root. Surgical treatment by very limited hemilaminectomy carries less than I per cent risk does not significantly weaken the supporting structure of the back and offers immediate relief of the lateralized nerve root pain. A more conservative attitude is held when low back pain predominates as spinal fusion then may be necessary Single nerve root section may be done to free a nerve from fibrotic adhesions and leaves no

The final discussion is interesting in the critical disabling functional loss analysis of other reports The authors consider it now well established that total involvement of either the 5th lumbar or 1st sacral nerve will usually produce objective sensory changes Foerster's dictum, while on a later page they state involvement of only one nerve does not often pro-Dandy s contributions on concealed discs and surgical excision of discs duce hypesthesia. are considered not well founded Primary sciatic neuritis and sacrollac strain are called clinical curiosities kellgren's dermatome pattern of re ferred pain from interspinous ligament injection is commended for its dermatome localization but on the preceding page the authors state that localized pain-is not very reliable in identifying the roots involved by herniation of nucleus pulposus. The orthopedic idea that narrowing of the 5th lumbar intervertebral foramen commonly causes nerve root pain is negatived by the usual finding of a herniated nucleus pulposus compressing the 5th nerve root when symptoms of this root involvement are pres ent It is stated that there can be no doubt that ent at is scatco that there can be no sound that the incidence of anomalies is greater in a series of patients complaining of low back and scratic pain patients complaining of for back and scaling path than in a control series " inasmuch as this condition seems to predispose to nucleus pulposus herniation although in itself does not cause nerve root symp-

Cervical herniations are presented somewhat briefly but with emphasis on the recent establish ment of small lateral hermation in the lower cervical region as a common cause of pain radiating from the neck over the shoulder and into the arm and hand with subjective sensation of paresthesia or numbness. As in the leg the pain and numbress follow a compressed single nerve root distribution and hyperthesia or hypalgesia may be demonstrated Surgical relici can be given, as in the lumbar herniation after trial of conservative measures Occasionally wile hermation of annulus as well as nucleus will cause cord or cauda equina compres ion and deman is prompt relief by surgical procedure I IAY KYIGAK.

"HE author of Acute Injuries of the Head is one I of the leading neurosurgeons of England. By training surgical background, and large personal experience in the field of cranlocerebral injuries he is thoroughly qualified to write on the subject of bead injuries

The book is addressed to the general practitioner and the general surgeon whom the author regards as vital links in the care of patients with cranial injuries The subject of craniocerebral injuries has been covered from every angle in this book. The chapters on the mechanisms of injury and pathology are splendid. Those portions of the book describing technical procedures and operations are clearly written and generously illustrated. Posttraumatic sequelae are thoroughly dealt with. The author has given very thoughtful, realistic discussion of the organic and the functional factors contributing to the typical postconcussion syndrome with helpful guides for expressing the relative role played by these two factors in any patient. Principles of treatment described in the book will have the approval of most neurosurgeons. This reviewer differs with the author's opinion regarding the value of subtemporal decompression and repeated appeal drainage in the treatment of closed head injuries but it must be recognized that these are still un settled issues. The author's style of writing is pleasing and invites further reading. He tends to avoid generalizations and prefers to make his points by numerous well chosen illustrative case records.

would be in regard to the arrangement of subject matter The book might be improved a bit, in the reviewer's opinion, by a change of certain chapter headings for instance, Chapter III which is titled might better be titled "Clinical Diagnosis Manifestations and Typical Clinical Syndromes Again, the arrangement of subject matter might be improved in one or two places for instance, the chapter on pathology deals only with pathology of cerebral injuries, whereas the pathology of cranial fractures is dealt with in a subsequent part of the book, describing the treatment of these fractures At another place in the book, under the subject head ing of Spinal Puncture," the author digresses far enough to discuss treatment of primary shock, transfusion, the management of associated visceral wounds, and the excision of compound fractures. At another place in the midst of a chapter on diag nears the author consumes one full page in discussing the indications for subtemporal decompression. The discussion itself is entirely proper but the place in which the author has introduced it in the book apnears to me untimely

If any criticism were to be made of the book it

These are of course minor considerations judged against the general excellence of the subject matter and can be corrected in subsequent editions. The book is of comfortable size and pleasant to handle

Active Populates of the Head, Their Diagnosis, T EATMENT Consent troots we forcette. By G. F. Rawbeldons, B.fc. (Masch.) F. R. C.S. (Eng.), Forward by Norman M. Dott, M. B. Beltimora, Md Williams & W. Rims & Co. 1945

Paper and printing are good Illustrators are numerous and excellent. The author in his prefer to the second edition, says I believe that an general practitioner will find perusal of this book as only valuable, but will find the subject interestme and even exciting. With that opinion, I come JOSTY E. SCULT

"HE fourth edition of Kunts' A Taplied of A Neuroanatomy' follows the traditional patters of introducing the gross topography of the perces system with comparative and embryological ser tions then of reviewing the histology of serves tissue and proceeding from peripheral nerve into the spinal cord to mount by several stages through the brain stem and emerge at the cerebral corter. Within the limits imposed by such a reposal soproach, in which, for example consentive chapter are devoted to nuclear connections of the crasic nerves the cerebellum the diencephalon, the opticonnections and the autonomic nervous system, the author presents a clear description of neurosustors without excessive detail and with a conche summiat the end of each chapter. This last unusual feature will doubtless be greatly appreciated by the but pressed medical student of today

Passing reference to the functional and clinical significance of structures is made throughout the text and an entire chapter is devoted to that of the cerebral cortex A laboratory guide is appended, together with a series of case histones illustrating the clinical aspects of injuries to the peripheral nerves, spinal cord and brain. Because all the brain lexions resulted from vascular disturbance the student may wonder why no reference to the blood supply of the nervous system was incorporated H. W. Mroom in the text.

IN the third edition of Kuntz' The Interest Interest System, presentation of the general and omy and physiology is succeeded by detailed dicussions of the innervation of each of the orpus visceral pain, histopathology disease, and sato nomic neurosurgery Specific citation of original articles is a constant feature and the one besided twenty pages of assembled references constitute a unique bibliography in the many aspects of the field.

In the preface mention is made of the temptation to give undue weight to recent contributions that is resisted in varying degrees to preserve a balance between the new and the old. The reviewer is one she would like to have seen this resistance related is the discussion of such topics as the terminal retorion and ground plexus and the sympathetic innervation of skeletal muscle

The book is recommended as a valuable reference work to everyone interested in the autonomic ac-II M. News a vous system

HE work described in Pulmonary Tuberculosis in the Adult by Max Pinner! is a welcome addition to the tuberculosis literature. The material has been wisely selected from the welter of divergent viewpoints and connected or really solded into a unit that is clearly presented easy to rad and understand; and one that compels an

Doctor Pinner states in the preface that he does theorbing interest in the subject. not pretend to have written a textbook or a guide to not pretend to have written a textbook or a guide to treatment or diagnosis, but aims more to stimulate interest in the form of an introduction to the dy namic process of tuberculosis His purpose has been fully realized. In addition to the many fascinating essays on the discase the author has given a val nable collection of short abstracts of important art

No worker in tuberculosis or chest diseases should e without this book, although the work does not les on the various topics. lave, nor pretend to have anything but general

The illustrations are adequate properly chosen usefulness for the surgeon and well reproduced The type, printing paper and binding are worthy of the high standards already set by the publisher

THE third revision by Stander of Teribook of Designation of Obstatrace represents the night edition of Williams Obstetrics but it is published under the present author's name since, as he states in the preface it embodies his teaching and practice and therefore he assumes full responsibility

This volume consists of 1200 pages of subject
matter with over 700 well chosen illustrations. The first 500 pages deal with the anatomy of the female pelvis, physiology development of the fetus and change occurring therewith endocrine function and their practical applications in obstetrics, and the conduct of preprancy and labor An excellent review of the subject of analgeous and anesthesia is included The following 700 pages are devoted to the pathology of pregnancy labor and the puer persum. Abnormal pelves and operative procedures are considered here. The actions on toxemias, extrauterine pregnancy and abnormal pelves are particularly comprehensive and embody the latest contributions on these subjects. One important omusion, however is noted under the subject of contracted pelves, namely the Hillis impression method All other methods for attempting to determine the relationship between the size of the fetal head and the maternal pelvis are described. The Hills impression method since it is the simplest and without the objection of vaginal manipulation, is by far the most practical and useful of all such man euvers, and should therefore, be included in all

POLISO 18 Typers, LOST DE 1925 ANT. Its letter speet Appeters By Man France M.D. Speedfeld, III. Charles Chocass, equipment By Man France M.D. Speedfeld, III. Charles Chocass, equipment of 1975 and 197 obstetrical textbooks.

Stander's third revision of Williams' Obstetrics brings it up to date with such recent advances as the importance of the Rh factor in obstetrics and the addition of penicillin and the sulfonamides to the obstetrician sarmamentarium but it also retains the simplicity of style and the clear concise presentation of the subject that has characterized this text in previous editions.

"HE volume entitled The Osseous System" is the fourth of a series of handbooks of roentgen diagnosis being published by the Year Book Publishers. As in previous volumes the material is so arranged that the illustrations are on the right hand page and the description and legends on the opposite side. The concise but lucid subject matter is illustrated by 432 figures on 148 plates all in the negative Throughout the text, the author emphasizes the pitfalls of diagnosis and arges that the occasional radiographer always think of the maxim

might it be besides what I think it is? The contents of the volume is divided into five sections technique principles of interpretation roentgen anatomy injuries to the skeletal system other than the spine the spine bone diseases and abnormalities in childhood bone diseases occurring principally in adult life. A short bibliography appears at the end of each section and an adequate

This volume is a handy sized modestly priced atlas and can be recommended to general practi index is appended tioners surgeons and internists as a diagnostic aid It should be regarded as indicated as a primer rather than an encyclopedia

HE author of Electrotherapy and Light Therapy is an outstanding authority in the field of physical medicine. The fifth edition of this work offers a concise presentation of all present day phases of physical medicine with special emphasis on elec-trotherapy and light therapy. The newer uses and methods of electronics, electrodiagnosis, ion transfer and ultraviolet radiation have all been incorporated The chapter on exercise has been considerably en larged and a new chapter on hypothermy has been added together with a revised glossary covering defi nitions of electrotherapy and light therapy muscle and nerve action and mechanotherapy Each chapter has been brought up to date. New illustrations have been added and obsolete ones omitted. The illustrations are excellent.

One of the peculiar features of the book which has enabled it to maintain a position of leadership for fifteen years, is the interesting manner in which the subject b presented It contains much valuable information, and it is a safe guide to place in the hands of the practitioner

TO OMERUTE STOTES. II NOR & RUSTIA DI NOR HY Viscret M Arther M.D. Chiago The Var Mook Palhabers, lac SUCCESSION OF LOWER TREASURE SITE OF LOTATIA OF PROPERTY OF LOWER TREASURE SITE OF THE CONTRACT OF THE CONTRAC

"HE subject of this book is physiology not physiology from above but physiology from below not physiology originating essentially to fill human needs and help suffering individuals but physiology as a branch of physical chemical sciences dealing with life as a physical, though exceedingly complex system, that may be subjected to scientific analysis like any other natural object." Quotation is from the preface of Physical Chemistry of Cells and Tissues by Rudolf Hoeber et al

The reviewer is very much in sympathy with the aims of this book. American science in general, is far too concerned with practical applications." Nature is a lady who must be wooed for her own worth before she will reveal herself. Certainly there is a tremendous need for such a book as we have here and a still greater need for people with the viewpoint of the authors of this excellent text. It is a book which must be bought by all who wish to understand what is now known about many important phases

of life processes.

The first or pages were written by David L. Hitch cock and deal essentially with physical chemistry of solutions He discusses diffusion in solution, reaction velocity thermodynamics, electromotive force, osmotic pressure, electrokinetics and distribution coefficients. Hitchcock stavs on broad and well trodden highways. This section is clearly written but parts of it are very scratchy and rather thin For example, the reviewer doubts that a reader who is not already familiar with thermodynamics could profit very much by reading the chapter on this subject too much territory is covered in the 12 pages This brevity is carried to extreme in the dis cussion of dielectric constants, dipole moments and the Deby Hueckel theory of strong electrolytes. Two pages are devoted to these subjects!

Section a which covers 150 pages was written by J B Bateman In this section Bateman deals with molecular forces determination of sizes and shapes of large molecules hydration, protein structure x ray diffraction analysis, the structure of crystals and fibers and surface monolayers. There is much excellent material in this section. The part dealing with crystal structure is especially informative Bateman covers many complex subjects and the reviewer appreciates the great difficulty of present ing these topics simply but it must be said that this section suffers from a lack of clarity

The strictly biological part of the book begins with Hoeber's section (141 pages) which deals with the penetration of cell membranes by organic non electrolytes by electrolytes by weak acids and bases by dyestuffs by water and finally he considers the chemistry and physics of plasma membranes. He brings to these subjects more than 40 years of experi ence and he has performed a great service to all of us summarize g with completeness and detail the zisting kn wiedge about cell membranes. Hoeber

Payan, at Constitute of Critis and Tissues. By Rudolf Hosbit With combinations of D. I. Hitchcack, J. B. Raterman, D. R. Codshitt and W. O. Foss. Philladelphia and Toronto The Bakistan Co. 643-

follows the Collander and Baerland impid-size theory" of cell membranes. He discusses active to passive uptake of substances and describes low the can be distinguished from each other. One came help but have the feeling after reading this section that future progress in the study of cell penetuha must involve a fuller consideration of the interior of cells. It appears that the penetration and actor of narcotics is very obscure and would execulty bee fit by such expansion

A section has been contributed by David 1 Goddard (71 pages) on the respiration of cells and tissues. Goddard a section is simply written den and up-to-date. He deals with the rate of remeating as limited by the rate of diffusion of crypts. The kinetics of activated reactions are discussed and the a short chapter on the nature of oxidation he da cusses respiratory ensymes. There follows a chapter on the relation between fermentation and recontion. Finally there is a chapter on the utilization of liberated energy This last is by necessity very is complete since our knowledge of this utilization and

the present exceedingly imperiect. W O Fenn has 75 pages on contractile tires with special reference to striated and smooth made. This is a well balanced and critical review of exerments and theories of muscle contraction. It spens from this review that there still remains much to be known about muscle contraction. Muscle physiologi has passed through several phases until now a less become a sophisticated science and one has to have background in several branches of science to appreciate all the modern developments. One can, inever note considerable recent progress and as Fem writes, "At last the contractile machinery is it come more than a structure which is pessively stri upon by lactic acid or some other metabolic probat It is as if steam had at last been admitted to the previously empty cylinders of the muscle machine

Hoeber concludes the book with a section (170 pages) on passive and active transfer in animal plant tresues. In this section be deals with intestee absorption, formation of urine, permeability of job surfaces of animals and plants, formation of dective juices and finally a discussion of some of the mechanisms which may be involved in active tresfers. Here again as in the section on cell membrand HITTERY B. Beil. there is a wealth of detail.

HE fourth edition of Christopher's A Testan 1 of Surgery an already well established strat ard text by eminent American authors, has been made an even more complete and currently cored basic volume for students and reference point for practitioners. This has been accomplished through the addition of sections devoted to recent military experiences as well as the modification of other sections on the basis of progress in both civilias and military surgery In view of the earliness of pub-

A TEXTROOR OF STREETY By American Ascher: Paint by Pederic Christopher BS M.D. FACS at all years of Leaden: W. B. Sacnders Co. 1945

cation following the end of World War II remark ably few statements will require considerable cor rection as a result of reports on military observations made available subsequent to completion of the present edition. This volume maintains the high standards of format and illustration which charac terized previous editions of the work.

## CLINICAL CONGRESS OF AMERICAN COLLEGE OF SURGEONS

W EDWARD GALLIE, President IRVIN ABELL, Louisville President-Elect

Committee on Arrangements
Howard Patterson Chairman Frank Glein Secretary

## PRELIMINARY PROGRAM FOR 1946 CLINICAL CONGRESS NEW YORK, SEPTEMBER 9 TO 13 1946

THE thirty-second Clinical Congress of the American College of Surgeons will be held in New York City at the Wal dorf Astoria from September 9 to 13. This will be the first Congress since the 1041 meeting in Boston. Between 1012 and 1015 the Congress was voluntarily enneelled each year in order to lessen the transportation difficulties and to conserve the time of medical and hospital personnel who were overburdened because of the absence of so many of their associates on duty with the armed forces. By autumn the majority of these will have returned and the time seems most auspicuous for a great postwar Congress. The preliminary announcement of the plans has been received with enthusiasm by both the military and civilian groups.

#### CLINICAL PROGRAM

Under the leadership of a strong and represent ative Committee on Arrangements, plans are under way for a complete and varied program for the five day meeting. The hospitals and medical schools will co-operate in scheduling operative and nonoperative clinics and demonstrations.

#### COMMITTEE ON ARRANGEMENTS

Howard Patterson, Chalmas Frank Glenn, Secretary Frank Adair Albert H. Aldridge Thomas M. Breman E. Jefferson Bross der George F. Cabill Henry W. Cave Ralph Colp Idward J. Donovan Merrill N. Foot John H. Garbock Charles A. Gordon George J. Hener J. William Hunton George H. Humphurys William F. MacFee John H. Mulbolland W. Barcley Parsons Otto Pickhardt Thomas H. Rassell Raymond P. Sullivan Howard C. Taylor, J. William Crawford White Philip D. Wilson

Visiting surgeons will have ample opportunity attend well arranged programs of many different kinds in several of the excellent hourtals in the Greater New York area. These programs vil include general and special demonstrations and as fractures, cancer maternal morbidity and end-result studies clinkopathologic and x-17 conferences newer diagnostic and therapeut procedures preoperative and postoperative say portive treatment anesthesa and recondition ing Those interested in operative clinics vil have an opportunity to observe newer technique and surgical procedures. A series of exhibit demonstrating the work of the medical schools and their affiliated hospitals will be available in study in the local hospitals during the medal, and the basic science departments of the medical schools will present graphic descriptions of ther work.

The program of each hospital will be amaging to cover subjects in general surgery obserted and gynecology fractures, orthopede surgery thoracic surgery neurosurgery genteemany surgery, ophthalmology and otdaryngology daily clinical bulletin will be published to how the presentation of subjects under these classifications so that the visiting surgeon may select the programs which he wishes to attend.

#### CONVOCATION AND PRESIDENTIAL MEETING

The opening evening session of the Chical Congress will be devoted to the combined production and the combined production. Since the left Congress in 1941 a total of 2 744 surgers have been received unto fellowally in selection, and to them in particular the Convocation on the opening night of the Congress will be a long antiogram event. Many of these new Fellows have been

serving with the armed forces. The formal initi ation ceremonies, always impressive, will be ex ceptionally so this year because of the large number of new Fellows accepted during the past four years who are expected to be present, in

addition to the 1946 group of initiates Officers, Regents, and Governors have remained in office since 1941 because of the cancel lation of annual meetings of the Fellows and Governors. Especial interest will also therefore beattached to the installation of the officers elect consisting of Dr Irvin Abell of Louisville, chair man of the Board of Regents as president Dr Leland S McKittrick of Boston as first vice president and Dr F Phinizy Calhoun of Atlanta

Dr W Edward Gallie of Toronto who has been as second vice president. president since November 1941 will give the Presidential Address.

### SCIENTIFIC SESSIONS

The scientific sessions to be held on Tuesday Wednesday and Thursday evenings, will be ad dressed by eminent surgeons and specialists, recognized as authorities in their fields. Special scientific meetings will be arranged on the same evenings for specialists in ophthalmologi and The newest developments in general and special fields will be presented in the well rounded program for these evening seamons. otolaryngology

Every afternoon from Monday through Thursday panel discussions led by recognized authorities in each field aided by well qualified collaborators, will be held Similar meetings held during past Congresses have been most successful largely because of the fact that they permit the particl pation of a large number of surgeons, thus in creasing the opportunines to learn from the ex

Preliminary plans include the holding of a penences of others. symposium on fractures and other traumas on one afternoon, and a symposium on cancer on another afternoon There is always wide interest in these special meetings. Plans for several new features have been discussed but cannot be announced until definite decisions have been made in co-operation with the Committee on Arrangements

#### FORUMS ON FUNDAMENTAL SURGICAL PROBLEMS

Great interest has already been shown in the plans for reviving the Forums on Fundamental Surgical Problems which were so popular at the Boston meeting Research activities have been retarded but not stopped during the war period

and the accumulation of the results of five years of work since the last Congress will certainly assure the presentation of intensely interesting maternal. The plan is to conduct these forums on Tuesday Wednesday Thursday and Friday mornings, and to include in them brief reports of original clinical and experimental observations relating to the broad aspects of surgery and sur gical specialties. No prepared discussions are planned but questions and comments will be invited. The enlistment of the interest of young men who are doing original work, through these forums, is one of the most beneficial results of these sessions which are now considered to be an indispensable feature of every Clinical Congress

### MEDICAL MOTION PICTURES

Medical motion picture exhibits will again be an appreciated feature of the Clinical Congress The latest available pictures showing surgical procedures and related subjects will be shown The accumulation of such pictures during the war has not been great but nevertheless a surprising number of new films are being received for review by the College and an interesting variety of edu cational pictures is assured The schedule will be arranged so as not to conflict with either the clin ical program at the hospitals or the scientific sessions. Both sound and silent standard and color films, will be shown all of which have been approved by the Committee on Medical Motion HOSPITAL CONFERENCES

The first formal session of the Clinical Congress Pictures. will be the opening meeting of the twenty fifth Hospital Standardization Conference. Dr W Edward Gallie of Toronto president of the Col lege, will preside. The hospital conferences will continue on Monday afternoon, with sessions following on Tuesday Wednesday and Thursday mornings, afternoons, and evenings.

Hospital administrators, members of governing boards, heads of the various hospital departments and their personnel nursing groups and many other persons directly or indirectly concerned about hospital progress will be interested in the discussions of current hospital problems. Na tional organizations representing various groups of hospital personnel will co-operate and participate in the meetings, which will include formal sessions, panel discussions round table confer ences, and open forums. ADVANCE REGISTRATION

The hospitals and medical schools of New York City afford accommodate -- for a large number of visiting surgeons, but to insure against over crowding attendance at the Congress will be limited to the number that can be comfortably accommodated at the clinica. The limit of at tendance will be based on a survey determining the available facilities in the participating has nitals and schools. It is therefore expected tha surveons who wish to attend the Congress will register in advance.

In accordance with a resolution adopted by the Board of Regents fellows of the College whose dues are paid to December 31 1046 initiates o the classes of rost rost tost rost and ros6 and fellows in military service will not be required to pay a registration fee for the 1046 Clinica Congress. For endorsed junior candidates the feis \$1.00. Surgeons, not fellows, who attend a invited cuests of the College, will pay a registra tion fee of Storo

For purposes of identification at the registration deak, fellows should present their fellowship cards Those surreons who pay the registration fee i advance will receive a formal receipt which they will exchange for a general admission card upon presentation at the registration deak in the Valdorf Astoria Hotel.

#### HEADQUARTERS AND TECHNICAL EXTURITION

Headquarters for the Congress will be established at the Weldorf Astoria where there are excellent facilities. The Technical Exhibition will be held on the Third Floor near the Gran-Ballroom. Leading manufacturers of surgica instruments and supplies, sutures, dressings pharmaceuticals, operating room equipment, x ray apparatus, hospital equipment of all kinds, and publishers of medical books will be represented in the exhibition, which will provide visiting sur meons and hospital people opportunities to inspeccarefully the newest and best products of al those industries which are helping to improve th service of hospitals and surgeons.

#### NEW YORK HOTELS AND THEIR PATES

Resides the Waldorf Astonia, there are a number of first class hotels which are conveniently located. In view of the extreme shortage of hote rooms which is expected still to prevail next September it is urged that reservations be made as soon as possible. The hotels which are true mended by the Committee appear in the loan ing lest

traus, J., and Briggs, W. A. Intraocular Foreign Bodies. Problems of Localization and Opera noures, Properties of Languages and SP tive Procedure. Bril J Ophik., 1945 29 557

In this article the authors discuss intraocular foreign bodies, the problems of their localisation and the operative procedures. They point out that the posterior approach for the extraction of intraocular oreign bodies, except in cases in which the foreign body is situated anterior to the lens, has become more popular since the war principally because new materials of low magnetic properties have been introduced into the manufacture of war instruments and munitions. Moreover metallic alloys of low magnetic properties will also most likely be ex tended into peacetime industry. They suggest a new method of localization which requires a less compleated and delicate apparatus than that of Sweet, s well as a new method of extraction. The limbal method is simple but it is not suitable for intra ocular foreign bodies of low magnetic quality or for nonmagnetic foreign bodies nor does it provide an accurate measurement of the point on the sclera to e incised from a fixed point on the eyeball

The authors recommend a method which gives the exact position of the foreign body in the eye to be operated on and the exact point to be incised on the siders (determined by I lateral x ray picture and I posterosnterior picture) To find the diameter of the ere, 3 lateral exposures are taken on the same film with the eye directed forward, upward, and down obeled the rest films the following data are obtained the radius of the eyeball the distance of the foreign body in front of or behind the equa tortal plane the meridian in which the foreign body has from the center of the eye and the distance of the foreign body from the center of the eye, procedure comprises the use of a conjunctival flap unuse exposure of and incision into the sciera, urface disthermy with 100 ma for 2 seconds (for coagulation) incision of the choroid and interrupted application of the magnet for about 2 seconds at 2second intervals for 50 times before discontinuance of the procedure as useless.

A duagram of a pair of forceps for the extraction of intraccular nonnagnetic foreign bodies is pre-

Von Sallmann Lat Penetration of Penicillin into the Eye; Further Studies. Arck Ophil. Cklc., sented

Previous studies on the penetration of penicillun into the eye after topical and systemic use were carried out with commercial preparations and the concentrations obtained in various parts of the eye were expressed in Oxford units A comparison of were capitased in Oziolu units in Oziolu units these results and those of the author is not possible since he used relatively crude preparations and titra

tion according to the Oxford method was not done The Fleming dilution method was used and the con centrations were given in micrograms per cubic Three local methods designed to introduce com centimeter

paratively high concentrations of the drug in the anterior segment of the eye were tested on rabbits and the results compared these methods were subconjunctival injection, ontophoresis, and applying cotton packs saturated with a penicillus solution

A comparison of the results with a solution of A comparison of the results with a southern of commercial sodium penicillin containing 5 000 units oper cubic centimeter showed that the highest conper cubic centimeter showed that the highest concentration was obtained in the aqueous by iontophoresis, and in the corner and the iris with the ciliary body by the prolonged application with cot ton packs. The lowest concentration in the aqueous cornes, and iris with the ciliary body was observed Extremely high concentrations were found in the after subconjunctival injection

cornes and the iris with the cliery body after the application with cotton packs saturated with a solu tion containing 20,000 Oxford units per cubic centi meter The content in the aqueous was also higher following this method than after any other

The ocular tissues and aqueous were almost com pletely free of penicillin 8 hours after iontophoresis with a solution containing 5 000 Oxford units per cubic centimeter and after a solution containing 20 000 Oxford units per cubic centimeter was applied by saturated cotton packs

I general nly traces were found in the lens and tro us after the real alm nistration

Dena F P : Tuberculosis of the Chorold with Inclusion of Bone Tis use (F berculosis d la corles et dudon de t Jid osen) trek is endutera Me 1945 3 207

A child 5 years of age was sent to the auther for camination on account of failin who hotolish bia, and redness of the left eye. Direct illumination howed a tumor of the auteric part of the cyball, involving chieff, the choroid General examination showed a primary tuberculo of the line which was active caudative slight in extent but mod rately a knoored. The Mant ux reaction was positive at 1 1000. Quarterily there had been a bemat gen us his semination of tubercle bacillifer in the Lingto the life eye.

Miter 6 in 1th of treatment at a taberculous h 11th the pulm nary on lith in as greatly im proved but an imbeychitis hall developed in the event of the name of the suspect specimens he well consil in I alwa able. The suspect specimens he well a chronic intainmant ty process with in lutes made un of various types of cells, preclominantly epithe

hard cell and koester's follicles

There were also fragments of lone in the chorsolbut there was no apparent reaction around them. There were evidently two independent findings a malary heratoromous tuberculosis of the chorn I and in taplastic cone it sue in the conjunctival to use of the chorold. Soon of the bone fragment were within the tuberculosis to use and some I them usts for it. It seems probable that the ost (cat) in I the chorold tissue took plee in emley no clife and that the lone tissue created a point of least resistance which favored the localitation I the tubercul i there. Versary G Monay M D.

Márquez, M The Technique and Clinical Value of Injection of Hypertonic Salt Solution into Tenon a Space in Detachment of the Relina (Tendez y alor clinic del la injectiones intantonian a hipertonicas en el despreni mient de la retina) A ch. At entir estre esquesa Mi 1013 3 207

A case of traumatic detachment of the retina is described in a boy of 13 years who was indured with a shotgun one of the abots lodging in the external part of the lower conjunctival called sac and cast ing great external hemorrhage and pressure on the eye-ball. There was detachment of more than half of the lower part if the retina with a small introduce per fration of the macula, through which the red color of the chorold could be seen. Central wish was abolished as well as more than half of the upper and a part of the internal which.

This case was treated by a preliminary injection for figure cent novocaln hydrochloride

followed by the Injection int. Tenon's spacestree of the properties at solution originally specified to the reduced to a per cent by the aid in official manufacture. This proved appetits to the solution present in following two Three injection presents of the solution of menty given. Three injections are given. The avoid field was rest red to absolute the solution of the solution

Lindsey J R Oppenheimer M J Wycis, H T., and Spiece E. A.: Receptor Apparatus of the Vestibulovasomotor Reaction

The labyrinthine reflexes upon the vegetative nervous system form an essential part of the various types of sickness caused by motion. Information is lacking regarding the receptor apparatus for such reflexes and therefore this study was undertaken

The observation had been made (Spiegel and Scale) that in cats in which for other reasons bilat eral puncture of the round windows had been made rotation failed to produce a postrotatory nystagmus, but still was able to produce a fall in the blood pressare. Since the otolithic appearatus might still have been the origin of the vasomotor reaction the present experiments were undertaken to determine the effect of labyrinthine stimulation on the blood pressure after the otoliths had been thrown off the maculas, to abolish the tonic labyrinthline reflexes

Guinea pigs were centrifuged according to the method of Wittmack to dislodge the otoliths. The animals were tested for postrotatory nystagmus, re flexes on linear acceleration and positional reflexes before and after centrifugation Centrifugation for I minute at 1 500 revolutions per minute resulted in the obliteration of the positional reflexes (righting of the head and compensatory eye movements) and partition complete loss of reflexes on linear accelera tion but in most of the animals the postroistory nystagmus remained undiminished, which indicated active responses from the semicircular canals How

ever a fall in the blood pressure could still be charted upon rotation. Histological preparations con firmed the dislogment of the otoliths from the maculas while in most instances the cupolas could

be observed in their normal positions The experiments show therefore, that the reflexes on the vasomotor system do not depend alone upon a of the vasibilities appearatus. However, they do not rule out the possibility that the otolithic appearance in the possibility that the otolithic appearance is the possibility of the possibility that the otolithic appearance is the possibility of the possibili ratus may contribute to the vasomotor reaction The vasomotor response had formerly been shown to penist after abolition of the postrotatory response but to disappear temporarily on the injection of cocaine in alcohol to paralyze the whole labyrinth or comme in account to paralyse are whether says much several interpretations are possible from these ex perments but it seems not improbable that the abyrinth functions as a whole as a receptor for reflexes on the vasomotor system and that the various receptors can substitute for each other

JOHN R LINDSAY M D

Druss J G: Aural Manifestations of Leucemia Arck Otolar Chic. 1945 42 167

An analytic review of the medical records of 148 subjects with leucemia admitted to the Mount Smai Hospital in New York, New York, over a period of

5 years yielded the following conclusions Aural complications of leucemia are more prevalent than is generally believed. They occurred in 25 of the 148 CRES reviewed or in 168 per cent. Routine cramination of the cars including functional tests of the cochlear and vestibular nerves would disclose an even greater incidence in all likelihood. The sural complications include diseases of the external mid dle, and internal ear and of the adjacent structures The pathological changes in the ear as elsewhere in the body are comprised chiefly of hemorrhage, cellular (leucemic) infiltration, and inflammation. Pathological changes in the ear may be revealed on histological examination even in cases in which there was no clinical evidence of aural disease at any

Ottic infections are comparatively more severe time during the illness in the leucemic than in the nonleucemic patient they not infrequently show a strong tendency to ward early invasion of the adjacent structures The diagnosis of acute mustoiditis in a leucemic subject may paradoxically be made more difficult by the presence of postauricular swelling and sagging of the bony external canal wall since these signs so well recognized as pathognomonic of supports tion in the mastold bone may under such circum stances also represent leucemic infiltration in the adjacent soft parts

Lindsay J R.: The Significance of a Positional Nyatagmus in Otoneurological Diagnosis. Le-

Postural vertigo and its accompanying positional nystagmus is the most common type of vestibular disturbance in diseases of the central nervous system. It occurs less frequently in peripheral ear

hisrascs. The syndrome can be on lucid during n utine neutional test. In kn wn lesion, central and peripheral in types of positional ny tarmu may be lifferentiated. #### Atkinson, M.: Ménière a Syndrome: Comrades d Results of Medical and Surgical Treatment. Irch Year Parchial Chic. 1016 to 101

The author reviews the various medical tresment in popular use for Mendre's exeducet ! clu le e salt-free d'et and dehydration, sodien fre let plus ammenium chloride low salt diet and ammonium ebloride, high pota lum diet, battert ntravenou ly and nic tinic ac L. It is believed that ach of these methods of treatment will give mid r improvement of vertico in from 61 to 00 per and

I rases. The incidence of improvement in dealing and in tunnitus varies from 0 to 16 per cent. Sees lating on the cause for the similarity of results cotained with these arious medical treatment the theory I a common ba le factor which is allered favorably by all of these treatments is suggested Increased capillary permeability is succested as seca factor and may be due to one of two cares anoxia from a d mini bed blood supply or senson tion t some f rm of protein r chemical. On the ba is the favorabl action of each of these vances medical treatments might be explained. The author has had better experience with nicotine and and hi tamine desensitization in appropriate cases that

Surgical treatments for the prevention of attacks

with other treatments

of vertigo are also discussed Pertmann a operation on the saccus ended aspest icus does not sacrifice hearing but has not met wat general favor probably because of 25 per critialiures. Rem val of foci I infection, lake recomended highly by me writ r has failed t gi em sult in the hands of others. Sectioning of the vestibular I rtlon if the eighth perce is critered because if its fail re t releve the dealness and tinnitu although the latter may sometimes be isproved Operations on the laby rinth comist of two types those which destroy the labyrunthine function completely and those which destroy only a part of the vestibular function. The former has the unde sirable result of destroying hearing and is unmultable in bilaterial cases or those with useful hearing in the affected ear. Experience with the second type of operation is not yet sufficient, but it seems to offer a safer and more logical procedure in that hearing is preserved.

In conclusion the author points out that medical treatment will relieve or control attacks of vertigo in about 80 per cent of cases and will give relief from tinnitus in about 20 per cent hearing can be improved in about 20 per cent of cases. Surgical treat ment is recommended only as a last resource to abolish attacks of vertigo

JOHN R. LINDSAY M.D.

Fowler E. P Early Diagnosis and the Arrest of Otoscierosis (Cilnical and Histological Otoscierosis) Arch. Otelar Chic., 1945 42 853

Otosclerosis is the name given to a disease of bone which begins in the bony wall of the labyrinthine capsule. It can be diagnosed only by the occurrence of deafness which is due to a limitation of mobility at the annular ligament which impedes the vibration of the stapes. Such signs as a pinkish glow from the promontory an apparent increase of hearing for bone conducted sounds a positive Gellé test, im movability of the malleus a normally patent custa chian tube scantiness of cerumen hairs and sweat glands in the external canal, and a family history of otosclerosis with no previous history of aural disease all point to a duagnosis of otosclerosis but all of these signs may be absent in the presence of otoscleroses and all may be present in the absence of otosclerosis

Available statistics based on histopathological examination (Guild) indicate that 7 55 per cent of white people harbor otosclerosis, but that only about 1 per cent have ankylosis of the stapes. Adequate statistics in the colored population are lacking but those available indicate a much lower incidence of otosclerosis possibly 1 per cent. The disease tends to be most active under the age of 20 and least active after the age of 60 years.

The only clinical indication of beginning ankylosis of the stapes is a slight lowering of the hearing acuity for the lower frequencies. In uncomplicated active dotoclerosis with ankylosis the loss of hearing progresses inversely with the frequency or pitch of the tone. There is as yet no knowledge as to the etiology A smills disease of one has not been found in other parts of its disease of the progression of

parts of the skeleton. In order to detect

In order to detect early otosclerosis every child should be examined when it enters school and a history of progressive deafness in the family should lead the observer to examine the child more frequently and to institute measures to correct any shoormali tes. Attention should be paid to hormone factors and certain vitamins and minerals especially around the age of puberty. There is no impressive evidence

that the fenestration operation arrests the otoscle rotic lesion.

JOHN R. LINDSAY M.D.

Shambaugh G E. Jr Fenestration Operation A Clinical Study of the Permanence of Ita Reaults. O Bull Northwest Univ M School 1945 19 259-

The history of the fenestration operation is the story of the search for a method of making a laby rinthine fistula that would remain open.

The early operations falled because new bone formation always closed the fistula with loss of hear ing improvement in a few weeks or months after operation. It is now possible to create a fistula in the bony labyrinth that will usually remain open. This is due to advances and changes in technique employed most recently shifts the position of the fenestra and the application of the skin flap so as to enhance the conduction of sound vibration from the tympanic membrane to the fistula. This has been employed in 173 operations

Closure of the fistula to sound occurred in 6 57 per cent of 800 consecutive flenstration operations. Analysis of these cases showed that with each improvement in technique the percentage of closure diminished. The majority of the closures occurred within the first year after operation and in only 2 cases did they occur later than two years after operation.

The entitusm most frequently levelled against the fenestration operation has been that the hearing results would be trainstory because of bony closure of the fistula. This prediction was borne out in part in the early operations done by the original Lempert technique. Successive improvements in technique, however have successively reduced the percentage of failures due to bony closure. With the technique used by the author during the past 2½ years 77 per cent of the cases permanently maintain a function ally wide open labyrinthine fistula with maximum hearing improvement while 86 per cent present a significant hearing improvement.

#### PRABANA

Whiteleather J. E.: Transitional Feithelial Gd Carcinoma of the Nasonharron, An J Inst. 1945 54 357

Tran itlenal enabelual cell carcinoma of the repharynx is not a rare disease. If ever the day nosis is often ma ! too late is r succes ful treatment The direct caffeet both males and females of all act and it is exceedingly malignant in children and roupe silult

The most common s te of the primary lesses is in or near the I was of Rosenmueller or in the plants geal torells. One of the earliest symptoms is rein able to obstruction of the custachian tube Later symptoms are referable to a nolynoid obstrocts to the nasopharynt invasion of the transal carm and metastases to the lymph nodes of the neck. D dark metastases are common

Radiation therapy is the accepted methol el treatment and offers the greatest hope at this ture whether it be complete arrest or rulliation. Patents who are treated before metastases or intracranial extension occurs can e pect the best results.

Sixteen cases of transitional epathelial cell cardnoma of the na sopharynx in patients of from 10 b 58 years I age are reported Metastases are present in all but a Six patients are still livme. Of these 3 have the disease and 3 are free of it. \cer of the latter has survived more than 30 months.

JOHN F DELIN MD

#### NECK

Means, J. H : Hyperophthalmorathic Grass Discuss A Int. M 1945 13 179-

Surveying the several phases r types of Gra of disease one may recognize among others, the followiner

- 1 Classic Graves disease, with ophthalmopathy thyrotoxicosis, and gotter
- 2 Graves disease with thyrotoxicosis but no
- 3 Hyperophthalmopathic Graves disease with hyperthyroidism, enthyroidism or hypothyroidism in which the ophthalmic phenomena are the most prominent.

The pathogenesis and etiology of the ophthalmopathy have not yet been definitely established The available evidence indicates that swelling of the orbital contents is a very important, if not the sole, factor concerned in proptosis of the globes. Weak ness of the rectus muscles probably also plays a part and the wide separation of the lids, too may be a factor. The orbital swelling is believed by many to be due to increase in fatt. Although the precise cause of the swelling in the ophthalmopathy of Graves disease has not been established with any degree of certainty it is very evident that the anterior lobe of the plittiatry gland has some relation to it.

From the point of view of diagnosis, the problem is not one of distinguishing between ethologically distinct types but of deciding in any given case, whether the ophthalmopathy or the thyrotoxicosis constitutes the greater menace to the patient. The manifestations which render the eye condition disquieting are those reflecting swelling and muscle involvement—bulging of the lids chemosis of the conjunctiva limitation of the coular movements, and diplopsa Lunitation of upward movement is the most impressive, and probably the most signifi

cant, of the muscle phenomena.

A more difficult diagnostic problem is that of recognizing cases in which the eyes are likely to enter the hyperophthalmopathic phase at a later date, with a view to prophylaris. Males are more prone to develop the hyperophthalmopathic phase than are females. The early occurrence of subjective ophthalmic symptoms should also suggest the possibility of an impending hyperophthalmopathic course. The early occurrence of chemios and in jection of the conjunctiva and of epiphora is also suggestive of the hyperophthalmopathic type whereas marked lid retraction phenomena with little or none of the phenomena due primarily to swelling favor the classic type.

The treatment of the hyperophthalmopathic type is specific and symptomatic. Thyroidectomy should be avoided in cases in which the development of a hyperophthalmopathic course is considered likely Enough cases follow this course postoperatively to justify the belief that the removal of the thyroid plays an important part in initiating it.

The administration of thyroid irradiation of the pitultary gland and administration of substances antagonistic to thyrotropin are among the specific

measures used in treatment.

Symptomatic treatment consists of adequate protection of the eyes, depleting measures (on the theory that edema of the orbital tissues may play a part) measures aimed at improving the strength of the extrinsic muscles and surgical procedures from tarsorrhaphy to enucleation. SAMULL KARN M.D.

Davis E. D. D., Lederman M., Harnett W. L. Woodman E. M. and Others. Discussion on the Treatment of Carcinoma of the Larynx, Proc. R. Sec. M. Lond., 1945, 38, 353

DAVIS reviews laryngofissure for early intrinsic carcinoma of the larynx and compares the results with those in cases treated by radium implantation. radiotherapy or radical laryngectomy. The most suitable cases for laryngofissure excision were those in which the growth was limited to the middle or anterior third of the vocal cord. Extension unward to the ventricular band or into the ventricle was no contraindication to excision, but extension to the subriottic area to the posterior commissure or across to the anterior commissure was regarded as a contraindication to this type of operation. The most successful excisions resulting in cures were those done for epidermoid carcinomas of the Grade z Broders type. All the operations were done under endotra cheal anesthesia with chloroform and ether isthmus of the thyroid was usually divided to facili tate tracheotomy a procedure no longer considered necessary in every case. When tracheotomy was performed the tube was always removed before the patient left the operating room. Extreme care was always taken to insure against the oozing of blood into the larynx. Packing of the larynx with gauze or division of the hyoid bone was considered poor surgery The alae of the thyroid were not removed, but the tissues about them were freed en bloc. In this series there were no deaths. Two of these cases were formerly treated with teleradium but showed recurrences and were then treated by laryngofissure. which resulted in 5 year cures

COLLIDGE recommended routine biopsy because senile tuberculosis mimics epithelioma of the laryny. Broders classification from the biopsy specimen if indicative of a Group IV carcinoma would suggest radical operation rather than laryngectomy After radiation therapy, operative technique may become more difficult and tissue devitalization may result in pharyngostenosis or necessitate plastic operations If radiation therapy fails a radical operation should be done rather than laryngofissure If general physical debility exists, patients are best treated by radiation therapy which should then be regarded as an alternative method. The technique of burying radium needles in the neck should be abandoned in favor of the teleradium beam which can be accurately controlled for dosage and causes minimal or no radionecrosis

LEDERMAN states that radiation therapy in early cases of intrusic excitonoms of the larynx can offer the patient as much as surgery and with less risk. Statistics were presented which matched Collidge's report of 70 per cent and 60 per cent 10 year sur

report of 70 per cent and 60 per cent to year su vivals after laryngofisture and laryngectom; HARNETT reported a series of 122 cases of cancer

HARNETT reported a series of 123 cases of cancer of the larynx not yet published. The sex ratio was

113 males to 10 females. The average age of the patients was 62 years. There were 57 patient with early, cancer of which 13 were treated by raileral surgers and 13 were alive after 4 years. Of the 10 in the latter group treated by palliative methods all were dead of the 10 treated by railium 5 survived and of the 13 treated by x ray 4 were alive. The operative mortality from larvingous ure (12 ca. e3).

wa 8 3 per cent.

Wooman believes that the method of opening a
window into the laryna and inserting radium needles
into the lesson should be defen led and not be alan
do ned. He also noted that x radiation may be given
through the window as a follow-up for recurrence

It is states that the preservation of the patients life rather than his one is build be considered before surgery a recommended. Septile can be better controlled now because of new drugs. Hence the result of radiation therapy will become more striking. After larging 1 ure radiation therapy should be given to decrease the percentage of recutrences.

Nicis reperts that patient treated with x ray therapy do not completely avoid damage to their voice as is commonly believed. They also suffer from the prolonged treatment and x ray reaction Perchoondrist; a complication after foradation Larrynoffs user supers ret ra lation therapy of the mangrance; so of low grad. Patient treated by the

Final Harmer method of radium implantates through a window in the largar made ancrendal recoveries and suffered little radiation acknow.

Wilson's results from either redisberge a surgery did not equal those reported. Whose lish that surgery should never be attempted after enssive radiotherapy. He also believes that there is reliable method of predetermining the radious lishty of a lexion.

Brown believes that surgery should be limited to simple carcinoma of the cord. The most laportist advances in laryngeal surgery consisted of the deination of tracheotomy by means of intubation and the control of bleeding with the cartery point.

CANTELD states that tracheotomy is of gent value because it diminishes the muscular activity of the pharmax and lars na and thereby promotes here healing. Days states that the Harmer Finni operation is superior to other forms of therapy because it entits

he to give the proper design of radium out the area to be treated whereas teleradium and say produces burning of the skin and other completion in the surrounding tissues. Colling said that the local use of radium case

Container said that the local use of radium case an irregular radiation effect and the tumor proper facility receive an homogenous dose

BINI MIN C P SHURROW MD

#### SURGERY OF THE NERVOUS SYSTEM

#### PERIPHERAL MERVES

Spuriing R. G: Peripheral Nerve Injuries. J Am M Ast 1945 129 1011

In the European theater of operations 15 per cent of all battle injuries to the extremities were complicated by nerve damage. If such injuries are mishandled the patient may be left with a useless, aneathetic limb therefore it was extremely important to set up a program of treatment for them

Immediate primary suture of a severed nerve is theoretically desirable, but in practice it is not a good plan because battle injuries are almost invariably associated with contusion of the nerve tissue. The optimum time for end to-end suture is between

the third and the month weeks after injury

It was not always possible to return patients with injury of the peripheral nerves to base hospitals for definitive treatment during the optimum period be cause these miuries were last on the list of priorities for evacuation among neurosurgical cases. These patients usually reached neurosurgical centers in England two to three weeks after wounding Mean while the wounds had been debrided and delayed wound closure done. Most of the definitive treat ment was given in England rather than the United States because the optimum time for repair would have passed before the latter could be reached However, the patients were usually sent to the United States for convalencence. Many serious wound infections or extensive injuries of the soft tissue requiring plastic repair were sent directly to the United States, by-passing England

Several points were outlined for the management of penpheral nerve injuries in the Manual of

Therapy for the European theater

In every wound of the extremities, damage to the nerve trunks must be considered and motor and sensory tests should be made.

2 Even in the presence of nerve injury the wound should be treated as any other soft tissue wound that is, by débridement and delayed closure.

- 3 If severed nerve ends are visualized during the debridement, they should be approximated if possible If the gap is too great to permit this both ends should be anchored to the soft tissue with fine steel or tantalum wire. This is to prevent retraction which sometimes complicates later end to-end suture. Metal sutures aid in later visualization by means of x rays.
- 4. Muscles and fascia should be approximated loosely over the exposed nerve trunk. No pack should be used. The wound should be closed later.
- 5 For transportation splints should be applied whether there is associated bone injury or not.
- 6 The condition of the nerves at operation and the procedure done should be noted on the emergency medical tag or on the cast.

The following principles of nerve repair were

Nerve ends should be trimmed until normal tu bules are visible. The ends should be approximated by epineural sutures with no tension on the suture

Hemostatis must be rigid. The use of a through and through suture (sling stitch) was optional. The recommended suture material was fine tantalum sure on a straumstic needle.

A small cuff of tantalum foil was usually placed over the suture line, although at one installation a

plasma clot (Tarlov's technique) was used

Removable splints were used rather than casts for the correction of deformities due to injuries. Extension of the flexed joint was begun at the end of the second week after operation and was completed by the fifth week.

Physiotherapy was applied both before and after operation Galvanic stimulation of denervated muscles will prevent atrophy and retard fibrosis and, accordingly this measure was used routinely, beginning with 15 brisk contractions daily and progressing to 30 contractions. Massage active and passive motion, and moist and dry heat were also used.

There were 6 245 bettle casualties with major nerve injuries hospitalized between D-day and V E day Of these 46 per cent were operated on over seas. The remainder were evacuated to the United States for definitive surgery usually because the neurosurgical centers abroad were overloaded.

In 47 per cent of the surgical cases the nerve was dound intact and neurolysis usually external was done. In the remaining cases the operation consisted of end to-end suture. The number of insurmountable nerve gaps amounted to 1 per cent, as opposed to the 10 per cent found among the cases in which operation was performed in the United States following the North African campaign. This is important because elective bone shortening to facilitate and to-end suture is not desirable and most nerve grafts are clinical failured.

Early nerve suture possesses three advantages over delayed suture (1) mobilization of the proximal and distal nerve segments is more readily achieved (2) fibroals in the wound, particularly in the nerve stumps, is minimized and (3) flexion of the contiguous joints is more easily accomplished.

The time lapse between wounding and neurosurgery varied from 28 days in the period after D-day to 42 days in the period of heavy fighting before \ E day The average for the whole period was 30 days which was longer than the optimum period but well within the upper limit of 90 days.

Primary wound healing occurred in 98 per cent of the cases, and demonstrated the wisdom of delaying neurosurgery for three or four weeks.

results he devised a surgical technique which was subsequently modified by Freeman and Watts in 1942. The latter believe that the correct procedure is the division of the anterior thalamocortical fibers, hoping thereby to disassociate the emotional and intellectual components of morbid thought processes

The authors then review a series of cases 100 in number and divided into 40 male and 51 female patients whose average age was 36 (their ages ranging from ro to 53 years). This material in cluded 4 case of melancholas 50 severe obsessional states, 2 epileptics subject to frequent attacks with impulsive outbursts and a general paretic, who having had treatment, developed a chronic hallucaness. The remaining 88 patients were suffering from schizophrenia 54 of them being cata toxic mostly of the excited hyperkinetic type who were sillen and withdrawn from reality although with occasional impetious and violent behavior Judged by ordinary prognostic standards all of these patients were considered hopeless chronic invalids.

The operative technique as described by Freeman and Watis was used throughout the series. From a technique standpoint the operation was a straight forward procedure with few complications the mot tality in the series being 4 per cent. The importance of expert postoperative management is stressed. The impression of the authors that the best results are achieved in cases showing signs of "mental tension is supported by this series. In the schusophrenia group periodic catatonics gave the best results. It is concluded that the value of the operation in certain types of emotional illness has been well paul Merkett, M.D.

Paul Merkett, M.D.

Frykholm, R.: The Treatment of Bilateral Acoustic Tumors. Acts chir result 1945 92 451

The incidence of bilateral acoustic tumors has been a subject of discussion for many years. In 1915 Henschen regarded the ratio of bilateral to unilateral acoustic tumors as being i in 10 Cushing in 1917 believed that many cases of unilateral tumors were not reported and that probably the ratio was closer to 1 in 100. In the clinic of Professor Olivecrona, in Stockholm during the period from 1922 to 1943, there were recorded 341 cases of unilateral and 6 cases of bilateral acoustic tumors.

The author discusses the cases of 54 patients with unlateral tumors, who were operated upon in this clinic during the period from 1937 to 1939. Radical enucleation of the tumor with preservation of the facial nerve was the objective, for in intracapular caudestion the nerve is nearly always sparred

Radical removal of the tumor with preservation of the facial nerve was done in 27 cases with 3 deaths, radical removal without preservation of the facial nerve was done in 14 cases with 3 deaths and intra capsular enucleation was done in 13 cases with 2 deaths.

This vast experience was available in the treat ment of 6 patients with bilateral tumor 3 of whom had a generalized neurofibromatosis. The cases are carefully recorded and it is apparent that they presented many surgical difficulties for 3 of the patients died within 2 months after operation. Frequently operation in two stages was necessary despite the bilateral approach and in no case was a radical removal accomplished on both sides with preservation of function in the facial nerves. The most satus factory result was obtained in the second case already reported in which the patient is alive 17 years after bilateral intracapsular enucleation. In 3 cases, the tumor on one side was radically removed the tumor on the other side was not dealt with Thirteen cases in which surgical treatment was carried out have been collected from the literature.

The syndrome presented in bilateral acoustic tumors is as would be expected except that the condition does not necessarily progress evenly on the two aldes. There is tinnitus nerve deafness, loss of nerve conductivity a beence or diminution of corneal reflexes, and roentgen evidence of dilatation of the internal acoustic meatur. These are followed by cerebellar signs, such as ataxla and nystagmus and finally there is increased intracranial pressure with vomiting and papilledems.

In the surgical treatment of acoustic tumors certain alms and restrictions must be observed

There should be a bilateral approach and the dura should not be closed unless both tumors are removed with their capsules. Complete encleation should be attempted only on a deaf ear Radical removal should not be undertaken if one facial nerve has already been paralyzed. If the patient is completely deaf, both tumors should be radically removed provided the facual nerve on the first side functions a two-stage operation may be indicated.

## MISCELLANEOUS

Alpers, B. J and Forster F M: Arteriorenous Ansurysm of the Great Gerebral Vein and Arteries of the Circle of Willis Formation by Junction of the Great Cerebral Vein and the Straight Sinus and of the Choroidal Arteries and Anomalous Branches of the Peaterior Gerebral Arteries. Arch. New Psychiat., Chic. 1945 54 181

The authors report a case of arteriovenous aneurysm involving the great cerebral vein (Galen) and the arteries of the circle of Willis This patient was an 18 year old male with a history of headaches for 18 years. His neurological study was essentially negative but x rays revealed a calcification in the right parieto eccipital region convolutional indentations of the inner table of the skull and complete destruction of the dorsum sellae and the posterior clinoid processes

Ventriculograms revealed an internal hydroceph alus with a calcified mass projecting into the posterior horn of the right lateral ventricle

Cramotomy was performed and the ventricle opened which revealed a mass of tortuous arteries

roots are cut bilaterally from Ta or Tu to Si local tendon shortening which remains can be cared for by manipulation or tenotomy With splints the flaccid legs can be stabilized to bear weight and with the addition of crutches the patients can learn to ure addition of distincts the patients can learn to walk. Because the bladder no longer empties except when it reaches its critical amount of filling or when deliberately stimulated the patients can remain dry

In the first of such operations attempted success was not complete because of difficulty in identifying the proper anterior roots, which were counted from what proper america none, which were countries from was thought to be S, upward. The patients expired from sepais arising from the urinary tract or bed sores. This has been eliminated in recent years by the use of tidal drainage with solutions M or G as irrigating fluid which also does away with bladder

calculi that otherwise occasionally form In dorsolumbar anterior rhizotomy the spinous process of Tu is identified. A bilateral laminectomy of Thand This done. After the dura is opened, the last teeth of the dentate ligament are identified since the intraspinal nerve which encloses it and leaves by the next dural opening below is the first leaves by the next dural opening below is the first leaves by the next dural opening below is the first leaves by the next dural opening in to S, are then lumbar All anterior roots from In to S, are then sectioned but none below S, should even be cut. If the patient is very deformed the laminectomy can be done in the lumber puncture position Pentothal sodium or an avertin base is the preferred anesthetic

Since the operation is permanently destructive it should be limited to those patients who have and tomical cord transection. The requirements for this diagnosis are complete absence of voluntary motor power complete sensory loss a predominantly flexor

or flexor adductor contraction in the abdominal muscles and in both legs in response to a noxious stimulus applied to the sole of either foot, and the summus applied to the sole of editer 1000, and the emptying of the bladder in accompaniment to this stimulus or other less noxious stimuli. Although the presence of an extensor thrust had been thought in the past to predicate neural cord connections above and below the lesions the author has found that its presence or absence is not necessarily an indication of anatomic cord transection and consequently it has no bearing on whether or not a given patient needs an anterior rhizotomy Ol primary importance is the elimination of infection and the establishment of a good general condition since the lack of a good general condition distorts the neurological status. Ten such rhizotomies have now been performed

by the author with the conversion of spartic para plegs to the flaced type in all cases. Twenty four hour urnary control without eatheter or drainage has been attained in all but 2 cases. Bed sores and pressure sores were healed or arrested in all cases pressure sores were meaned of street have developed before operation Two patients have developed bowel control so that defectation occurs only once a day at a predetermined hour. Three others are well on their way to attaining this end on their way to attaining this end in the others are well author matter and the control of either walking with splints and crutches or learning

Other patients have not been operated on because of the inability to control sepsis or hypoproteinemia, to do so or because of inadequate intelligence on the part of

the patient or ability to get along fairly well in spite of spasticity

and venus in the region of the glomus. More of the ventricle was incised which exposed a mass of vascular abnormalities lying against the tentorium with the vascular stem of attachment toward the midline.

The patient succumbed a days following operation, and necropay studies were done. These revealed an extensive aneutym arising from the junction of the great cerebral vein (Galen) with the straight sinus, and direct communications that the straight sinus and direct communications that the straight sinus sinuspants of the straight sinuspants of the straight sinuspants are straight sinuspants. The straight sinuspants are straight sinuspants are straight sinuspants and straight sinuspants are straight sinuspants and sending branches into the aneutrons.

Only s cases of a similar type of artenovenous aneutyam have previously been reported and both of these were associated with an internal hydrocephalus, the mechanism of which has not been adquately explained Howard A. Browx, M. D.

Gantt, W. H., and Marshall, E. K., Jr.: Toxicity of Sulfanilamide on Higher Nervous Activity Bull Johns Hopkins Heep. 045, 77, 104.

The authors found that the oral administration of large does of sulfanliantic considerably executing the therapeutic does produced a generally depressing action upon the conditional reflexes in dogs. Two dogs with previously well established salivary conditional reflexes and 2 dogs with corebellar motor conditional reflexes and 2 dogs with corebellar motor conditional reflexes and 2 dogs with cerebellar motor conditional reflexes became attails when given 0.5 gm of sulfanliantide per kilogram of body weight. The diminished conditional reflexes returned to normal the day following the experiment and there was no permanent impairment of cortical function.

Speigel, I J., and Lewin, P : Tourniquet Paralysis.

J. Am. H. Att., 1045, 120, 432

The authors believe that paralysis of a peripheral nerve follows the application of a tourniquet for hemostatic purposes more often than would be suggested by review of the literature. The reason for this is that most of the lessons produced by the tourniquet are only transitory.

niquet are only transitory.

Three cases of peripheral nerve paralysis presumed to be due to application of a fourniquet are described in detail furthermore in each case the particular nerve involved was surgically explored and visual isced. Neuromas were found on the nerve in a cases with thinning of the nerve structure below the lesion and in the third case the nerve was found to be embedded in soar tissue. The beson was so extensive in a sill of the cases that end to-end suture could not be accomplished because of the long length of nerve that would have to be sacrificed and it then seemed that the peripheral nerve injury would be permanent. Pathological investigation of the nerve lesion was not feasible for none of the nerve was removed. The time of operation was relatively uncertain but fin?

cases the tourniquet was supposed to have been plied for approximately 114 hours and m the fin case for approximately xx minutes.

In spite of these lesions the tourninger has a considered a very important adjunct in surpol mocedure on tendons nerves bones and joint

ADMINI VERMICICALES MIN

Munro D: The Reinbilltation of Patient Tent Paralyzed Below the Waht, with Speed let erence to Making Them Ambulatory as Capable of Earning Their Living. It Exp. J. M. 1945, 133, 453.

With proper treatment all patients with him, a the spinal cord who are intelligent, co-openire, an have the use of their shoulders, arms, and had or be made to live a socially useful entirest.

Among a series of say patients with thereich, but or a start ord detaces observed at the base City Hospital 59 cases were analyzed Tey-chosen according to the following criters we tient must have lived 90 days after the cost of disease he must have been rendered hospake doing gainful work and the lesion must have below the second thoracide level. The present aid is concerned only with complete anatonic traces too of the cord.

Following recovery from spinal shock, patent with anatomic transection develop a mass min or "maximal flexor response to a minimal sensor stimulus , provided the state of nutrition is good as no major infection is present. This refler counts dorsification of the great toe flexion of the anile re knee and adduction and flexion of the hip. It flexor and extensor tendon reflexes are both lype active the flevor muscles are hypertonic while the extensors have normal tone. In addition there contraction of the abdominal muscles, which sta ulates the urinary bladder and causes it to enge regardless of the amount it contains. The are leaves the bladder so rapidly that even if an bhy catheter is in place it escapes around it. Thus, the patients cannot be kept dry as long as the ser reflex remains active and since they are constant wet, bed sores remain a problem. The boxes is empty at unpredictable intervals so that the paties is always soiled with feces.

is a may a source with reces.

However if it he mass reflex and its effects orbicounteracted, the patient can be made analysis with splints. The bladder and bowers can also brought under sufficient control so that the person be trained to get through the night when can be trained to get through the night when setting were and through the day without reflex solded or having to empty his bladder more than every three hours.

The mass reflex is best eliminated by the kirs spinal division of the anterior spinal root. The stateds the logical point, the motor side of the rich arc, and converts the byperionic spiral capacity int a flaced by parapelgis. It also begin massed as the reflex activity to the abdomain massed as bladder and thus controls the latter. All anterio roots are cut bilaterally from T<sub>m</sub> or T<sub>m</sub> to S<sub>1</sub>. Any local tendon shortening which remains can be cared for by manipulation or tenotomy. With splints the flaccid legs can be stabilized to bear weight and with the addition of crutches the patients can learn to walk. Because the bladder no longer empties except when it reaches its critical amount of filling or when deliberately stimulated the patients can remain dry

In the first of such operations attempted success was not complete because of difficulty in identifying the proper anterior roots which were counted from what was thought to be S<sub>a</sub> upward. The patients expired from sepsis arising from the urinary tract or bed sores. This has been eliminated in recent years by the use of tidal drainage with solutions M or G as impating fluid which also does away with bladder calcult that otherwise occasionally form.

In dorsolumbar antenor rhizotomy the spinous process of T<sub>11</sub> is identified A bilateral laminectomy of T<sub>11</sub> and T<sub>11</sub> is done After the dura is opened the last teeth of the dentate ligament are identified, ance the intraspinal nerve which encloses it and leaves by the next dural opening below is the first lumbar. All antenor roots from T<sub>11</sub> to S<sub>1</sub> are then sectioned but none below S<sub>2</sub> should even be cut. If the patient is very deformed the laminectomy can be done in the lumbar puncture position. Pentothal sodium or an avertin base is the preferred anesthetic.

Since the operation is permanently destructive it should be limited to those patients who have and tomical cord transection. The requirements for this diagnosis are complete absence of voluntary motor power complete sensory loss a predominantly fixor

or flexor adductor contraction in the abdominal muscles and in both legs in response to a noxious stimulus applied to the sole of either foot, and the emptying of the bladder in accompaniment to this stimulus or other less noxious stimulu. Although the presence of an extensor thrust had been thought in the past to predicate neural cord connections above and below the lesions the author has found that its presence or absence is not necessarily an indication of anatomic cord transection and consequently it has no bearing on whether or not a given patient needs an anterior rhizotomy. Of primary importance is the elimination of infection and the establishment of a good general condition since the lack of a good general condition distorts the neurological status

Ten such thizotomies have now been performed by the author with the conversion of spastic pars plegia to the flaccid type in all cases. Twenty-four hour unnary control without catheter or drainage has been attained in all but 2 cases. Bed sores and pressure sores were healed or arrested in all cases before operation. Two patients have developed bowel control so that defecation occurs only once a day at a predetermined hour. Three others are well on their way to attaining this end. In the others sufficient time has not yet elapsed. All but 2 are either walking with splints and crutches or learning to do so.

Other patients have not been operated on because of the inability to control sepsis or hypoproteinemia, or because of inadequate intelligence on the part of the patient or ability to get along fairly well in spite of speaticity.

ROWER E. GREEN M.D.

# SURGERY OF THE THORAX

#### CHEST WALL AND BREAST

Daland, E. M : Some Unusual Aspects of Cancer of the Breast N England J M 1945 233 515

From previously collected data the author found that there is a much greater life expectancy in patients with carcinoma of the breast who are oper ated upon than in those who go untreated. A radical mastectomy is considered much superior to a simple mastectomy is reserved as a palliative measure, but x ray therapy is considered better than simple mastectomy. X-ray therapy is not tolerated well by elderly patients and this group is treated by simple amputation of the breast if a radical operation is considered too formdishle.

Three cases of carcinoma of the breast in patients under 19 years of age are reported, also a recurrence 34 years after radical mastectomy and 2 cases of penistent recurrence of low grade cancer over periods of 24 and 10 years respectively.

EARL O LATHER, M.D.

Röden, S.: On Cancer of the Breast, with Special Reference to the Results of Different Methods of Treatment. Acts radial Stockh 1944 57 5

The author has exhaustively studied 343 cases of carcinoms of the breast treated between 1911 and 1933 The patients operated upon in 1928 and later have generally been subjected to annual examina tions. The material was classified according to Steinthal group I (SI) small and slowly growing larger tumors not fixed to the surroundings and without microscopic metastasis to the axilla group a (SII) tumors with axillary metastasis as disclosed by microscopic examination their size being too limited to be classified in Group 3 group 3 (SILI) large and rapidly growing tumors fixed to the skin and under lying tissue with axillary metastases also all tumors with metastases in the force supraclavicularis and further away. There was a total of 141 cases (SI max SII mad and SIII 44)

Operative treatment was given according to Halsted's technique. Electrosurgery was used in 10 cases only. There was a primary mortality of 2.6

per cent.

X my therapy has changed throughout the years and on the whole the donage has been increased. Ara rule, therapy can be confined to two fields. The radiation is arranged tangentially to the wall of the breast to lessen the rask of radiation lesions of the lungs. The treatment includes one preoperative and three postoperative series.

There were 127 patients treated by operation alone, 98 by operation and postoperative roentgen treatment, and 118 had roentgen treatment before and after radical surgery

Of 59 patients in group SI treated by surgery alone 78 per cent survived 5 years and 55 s per cent survived to years. After to years death due to eace, causes was as frequent as death due to causer. Of patients in group SIH treated by operation alone, if died within a years.

Of 38 patients in group SI given postopeni, a irradiation, 71 per cent survived 5 years and 48 per cent survived 10 years of 51 in group SII, 153 per cent survived 5 years, and 13 3 per cent survived 6 years, and 13 3 per cent survived 10 years and of the 9 in group SIII none survive more than 3 years.

The patients treated by imalistion prespensing and postoperatively included & B in group SI is group SI and 18 in group SIII of the six group oper cent survived y years and 76 year cent servived y years and 76 year cent servived y years, but the figures (or to year at most year, but he figures (or to year at most years) and 9.78 per cent survived y years and 9.78 per cent survived y years. Other in group SIII none survived for years. The strength is all cases whether the patient died of case or from other causes.

The location of the tumor in the breast in reints to its degree of malignancy was a follow; (1) ago lateral quadrant,  $s_1 \in (4.8\%)$  cases less malignat and go (6.3.4%) more malignant (2) upper moisi quadrant,  $s_2 \in (3.8\%)$  cases less, and  $g_2 \in (4.8\%)$  cases more malignant (3) lower lateral quadrant (6.0.8%) cases less, and  $s_2 \in (6.0.8\%)$  cases less, and  $s_3 \in (6.0.8\%)$  cases less and  $s_3 \in (6.0.8\%)$  cases less, and  $s_3 \in (6.0.8\%)$  cases less and  $s_3 \in$ 

Data were available in 150 cases of neutron: de cases had recurrence or regional mentatuses and passes had datant metatuses. The recurrence as regional metastases made their appearance on average of 16 months after operation while the famouths. The patients in the group SI developed recurrences or metastases appeared in an average of 10 months. The patients in the group SI developed recurrences or metastases later than those is group SII as avoidable expected.

EARL O LABORE, M.D.

## TRACHEA, LUNGS, AND PLEURA

Consnt, J. S., and Dale, G.: Closed Extrapleari Pneumonolysis. J. Therac. Surg. 945, 14 JH

Closed intrapleural pocumonolysis established self as a safe and technically satisfactory morder which from hemorrhaps edisson and substance emphysema the complications vary little from the occurring during the course of meanocharat then pin patients without adhesions. The procedure is a very low mortality. There is less information, he were regarding the technical results and completions of extrapleural dissection of short pelmona attachments and those to which portions of the heat are adherent over a relatively wide area.

The author's report is based on 50 operators a which some degree of extrapleural dissection superformed. They represent all instances in helthis procedure was used in 143 consecutive intra pleural pneumonolyses The attachments in these 50 cases were unsuitable for division by the accepted certeria for intrapleural pneumonolysis and under ordinary circumstances these cases would not have been explored It was possible to obtain satisfactory collapse in 35 or 70 per cent of them by extrapleural collapse in 35 or 70 per cent of them by extrapleural collapse in 36 or 70 per cent of them by extrapleural collapse in 35 or 70 per cent of them by extrapleural collapse. achieved in 37 cases. If the number performed for ex horatory purposes (13) is omitted the operation morecoded in 5t of 37 cases or in 84 per cent of the

cases in which an extensive or complete dissection No postoperative fluid was noted in 26 cases Transient effusion occurred in 15 instances Twenty was possible. operations were followed by temperatures of over

100.4 F which lasted no more than I week except in the instances in which bloody effusion and staph ) lococcurs empyema occurred The latter was probably the result of damage to the lung parenchyma in the extremely firm short band Closed drainage was

Considerable postoperative bleeding followed the operation in 3 of the patients who had partial disnecessary section (23 per cent) and in 3 patients in the other two groups (8 per cent) These percentages suggest the various natures of the attachments The patients with attachments which after exploration are found to be too dangerous to dissect also appear to be the ones associated with the greater percentage of postoperative hemorrhagic effusion, even though the operation is not persisted in When extensive or complete dissection is possible postoperative ooxing quently vascular and it is suggested that the normal is rather infrequent respiratory tug at the denuded line of attachment when exaggerated by coughing and occasional vom iting has the opportunity of rupturing vessels and lossening the congulum following cautengation of

There were 6 cases of empyems 5 of which were the bleeding points tuberculous All of them developed 4 or more months after the procedure One case of staphylococcus aureus empyema occurred postoperatively

As to the technique a new type of sponge carrier and dissector previously described by the authors was used in 45 of the 50 operations. The Corylles pneumonolysis unit was used in nearly all of the

Brantigan O C.: Resection of the Lung in the nugan U U: Resocution of Lang in the Treatment of Pulmonary Tuberculosis. Arch

Tuberculosis is a systemic infectious disease caused by a specific micro-organism. It most often lavolves the lung and is usually bilateral, but, fortunately the major disease area is predominantly unllateral and often unilobar The application of adequate medical measures supplemented by simple surgical procedures will arrest or cure carly pul monary tuberculosis in most cases. Often in the later stages of the disease irreversible structural

changes occur in the bronchisl system and cause the failure of simple therapeutic measures

Accurate diagnosis is extremely important in recognizing irreversible structural changes in the lungs and bronchial system The use of tomog raph) bronchograph) determinations of intra cavitary pressure bronchoscopy bronchospirom ctry and diagnostic pneumothorax as indicated will lead to the correct diagnosis of pulmonary Only with an accurate diagnosis can the outcome of surgical treatment be predicted

Pulmonary resection is the only form of treatment that can be used effectively when pneumothorax or phrenic paralysis with or without pneumoperi toneum does not control basilar disease a cavity against the mediastinal surface in the lower half of the chest, or a cavity in the middle portion of a lung The isolated tuberculoma represents a localized form of pulmonary tuberculosis and it is perhaps the only condition in which all of the diseased tissue can

Controversy is invited when lobectomy is suggest ed for the treatment of a tension cavity and of unibe excised lateral or unilohar disease in a young person. Real contention and perhaps just criticism are encounter ed when lobectomy of the upper lobe is elected as the

method of treatment instead of thoracoplasty The criticism of elective lobectomy of the upper lobe for tuberculosis must not be allowed to react generally against pulmonary resection for tuber culosis. Good results in the whole field of medical and surgical practice depend primarily on the treat ment instituted early in the course of any disease.

Nine cases are reported in which resection of the lung was indicated for the treatment of pulmonary tuberculosis. One case resulted in death patient had been subjected to a bilateral pneumothorax and a thoracoplasty in a period of 8 years, before undergoing lobectomy performed a year after the final stage of the thoracoplasty was done. If the fadure of the thoracoplasty could have been pre dicted after the failure of the pneurothorax, pneu monectomy could have been performed as a primary type of treatment In 1 of the cases in which removal of a tuberculoms was included excellent postopers The remaining 7 cases showed that the patients were definitely benefited tive recovery occurred even though the disease was not cured in every case In 5 of the 9 cases reported the patients had endoin 5 of the o cases reported the patients had empo-bronchial disease. When tuberculous disease of the bronchial stump occurs, there is always the danger of the formation of fistules months or years after the operation Endobronchial disease often responds to the bronchoscopic application of silver nitrate even when an infected lung is distal.

Dissection of the bilar structures, which permits individual ligation of the pulmonary artery and veins and also adequate suture of the bronchus with silk, has greatly reduced the development of bron chial fistulas. The dissection in persons with tuber culosis has been uniformly easier than dissection in persons with other pulmonary conditions which re

quire lobectomy or pneumonectomy. Unfortunate by tuberculous disease often a located un the upper portion of the lower lobe which places it at the region of the incomplete feasure. As every effort must be made to avoid cutting into tuberculous tissue, the resection, therefore, must frequently be carried into the remaining healthy lobe. Technically it is often less difficult to do a pneumonectomy.

No drainage is used in cases of pneumonectomy and lobectomy of the upper lobe, since there is no method of immediately obliterating the pleural space. Two grams of sulfanllanide and from 190 to 500 cc. of chloroszodin (1 to 3,300 in sodium tetradecyl sulfate (1 to 500) are placed in the pleural cavity for bacterickial effect. The same drugs and solutions are placed in the pleural cavity when a lobectomy of the lower lobe is done even though it is drained. If the remaining lobes are freed completely from the parietal pleura the pleural space can be obliterated quickly by the use of a low negative pressure suction apparatus. Obliteration of the pleural space usually will prevent both propenie and tuberculous infections. It also offers some assurance against opening of the bronchiel stump

Ether or gas or oxygen and ether (given intra tracheally) is preferred for the anesthesa. One must try to prevent the aspiration of secretors into the other parts of the lung. After operation the patients are given carbon doxide inhalations and encouraged to cough and move frequently in order to forestall pulmonary complications. The patients receive 500 c.c. of whole citrated blood s4 hours before opera tion and from 500 to 1000 cc. of blood during the operation. They are placed in an oxygen tent 34.

hours postoperatively

The necessity or desirability of thoracoplasty following pulmonary resection must be considered seriously. Overdistention of the remaining pulmonary resection must be considered seriously. Overdistention of the remaining diseased lobe, whereas with thora copiasty it is well known that collapse of the apical region brings about relaxation throughout the whole cheat and favor continued healing of any remaining diseased area. On the other hand, it should be clearly recognized that the best results from lobect tomy in tuberculosis will come from treatment of early or midmial lesions. Lex Puller M.D.

Smyth, C. J., and Billingslea, T. H.: The Treatment of Lung Abscesses with Penicillin. J Am 11 Am 945, 129 005

Cases of lung abscesses treated with penicillin previously reported are reviewed and 4 new cases which the authors observed during the past 20 marks are reported.

months, are reported
Thirty-one cases of lung abscesses treated with
penicillin had been found in the literature, of which
13 were cured 8 improved and to aboved no im
provement. A table summarating these cases and
including most of the pertinent data presented in the
original report is given.

The 4 patients with lung abscuses who were observed by the authors made satisfactory recommended in transport to the following the long continued intrammediate sheet acres is returned to the following the continued in the following the continued in the continue

#### Poppe, J. K.: Limitations of Penicillin in Lapyerna. J. Am. M. Agr., 945, 189, 435.

Penicillia has undoubted value in prevatue empreus when it is administred in large quattes during the inciplent stages before fruit pas in formed. This is true especially of postpuenose pleural effusions of the pneumocococ type. Pet cillin is also of value in cases of potential containtion of the pleural space following surpical palacour resection and trummatic insuries of the hast.

The period of greatest value, however appear is be during the incipient stages of the infection prefer ably even before a pleural effusion has developed h is also valuable during the developmental stages of a pleural effusion when the fluid remains this sad clear with relatively few pus cells and a sterk culture. The formation of fluid and positive culture should decrease rapidly within a few days if the penicillin treatment is to be successful in preventing an empyema. The best results seem to ke obtained by a combination of parenteral and himpleural administration of the penicillin, with emplet placed on the parenteral route. Intrapleural ministration alone has not proved adequate. The use of penicillin to avoid drainage of a collector of thick intrapleural pus appears to represent poor judgment and undue optimism. Admittedly the can be rendered permanently sterile in a certain number of cases with tremendous doses of penicilia carried out over a long period of time at great espense to the patient for both the penicillia and hospitalization The most discouraging part of soci treatment is the tendency toward an umatisfactory result, even after the time effort, and money have been expended.

A trial of a or 3 weeks with daily penicillis doarpy of over 100,000 units plus intrapleural layerious of penicillin in the presence of a plearal effusion seen sufficient in most of these cases of potential empress By the end of this time e ther the infection should be completely cured or the empress drained if spain

and symptoms of intrapleural infection persist More than a week of hospitalization will still be required after the penicillin has been stopped in order to watch for latent empyems of which the symptoms have been masked by the penicilin action three per cent of Poppe's cases represent recurrences which developed 1 or 2 weeks after the penicillin

A sterile, dry nontoxic empyema cavity following the administration of large quantities of penicillin was stonned over long periods of time represents one of the most difficult problems. It simulates the unexpandable hing familiar to those dealing with tuberculous pleural effusions associated with artificial pneu

The author a experience with penicillin in over 150 carefully evaluated cases of pulmonary infections of mothorax. all types including empyemas lung abscesses, and bronchicctasis has shown that penicillin does not alter the surgical principles of treatment in any way Pus must be drauned after it is definitely established and chronically diseased tissue which is irreversibly

damaged and replaced by scar tissue must be excreed Patients who have been cured of their empyemas by penicillin should be carefully observed for at least a two weeks period for a possible recur rence. Any toxic or nontoxic turbid pleural effusion containing polymorphonuclear cells following a pyggenic infection treated with penicillin should be surgically drained even though the pus is sterile on

Indications for Surgery in Penetrating culture. Chest Wounds. Brit. If J 1945 2 521

The most important object in the treatment of lajures involving the pleura is early pulmonary ro-expansion By this means pleural infection will be limited and respiratory efficiency restored evidence, however, suggests that the prognous of penetrating wounds is influenced as much by the

condition of the lung as by that of the pleurs. Expansion of the lung is slower after penetrating wounds than after nonpenetrating wounds, irrespec tive of the presence of infection In both hemothorax and hemopneumothorax, pulmonary re-expansion is less rapid after penetrating wounds. In total hemopneumothorax the prognosis is good in the case of nonpenetrating in juries but after penetrating wounds the chances of persistent pulmonary collapse are high even in the absence of infection. This is the type of case which most frequently calls for surgical evacu atton of the pleural hematoma In most cases this difference is due to pulmonary injury which is not always recognized and treatment directed to the pleurs alone will not always result in re-expansion of the lung Difficulty in resolution of the hemopneu mothorax nearly always means pulmonary injury

The prognosts of penetrating wounds, moreover is with bronchopleural tistula. worse than that of nonpenetrating injuries because pulmonary re-expansion is slower and pleural infec tion is more likely Elimination of the pleural space

is of such significance that it is reasonable to regard early pulmonary re-expansion as even more impor tant than avoidance of infection. The former is a more useful means of promoting the latter and the prognosis of localized basal empyema is much better than that of persistent total hemopneumothorax

Pulmonary contusion and laceration on the other even if the latter remains sterile. hand are important causes of delayed expansion of the lung and are nearly siways found in the condi

Penetrating wounds of the upper lobe have the tion of unresolved hemothorax worst prognosis and are nearly always present with total or apical unresolved hemothorax If this per sists for more than two weeks surgical evacuation is indicated in all cases except those of basal hemo-

The main principles of treatment of penetrating wounds therefore are early elimination of pneumothorax thorax and hemothorax and early surgical débride ment of large wounds of the lung and pleurs STEPHEN A. ZITMAN M D

# HEART AND PERICARDIUM

Trent J C.: Surgical Therapy on the Patent Duc tus Arteriosus Report of 5 Cases. Arch. Surg

A patent ductus arteriosus is a constant threat to life if allowed to persist. The early diagnosis of un complicated patent ductus arteriosus is important, therefore and can be made in almost 100 per cent of the cases if the following criteria are present (t) ma chinery murmur (2) thrill in the pulmonary area (3) enlarged pulmonary artery (4) enlarged and pul sating pulmonary versels (5) enlarged heart (6) in creased pulse pressure (7) stunting of growth (8) absence of cyanosis and clubbing of fingers (9) normal electrocardiogram and (10) a history of heart disease from early childhood Not all these criteria

The presence of a machinery murmur is listed by may be present in every case. most observers as essential for the diagnosis though in rare instances the diagnosis may be made without it, such diagnoses remain open to question

until proved by autopsy or operation.

Surgical therapy is not applicable in all cases of patent ductus arteriosus. As a rule only in those cases in which the patent ductus is uncomplicated by other serious developmental defects is ligation suit

All methods employed to date, short of complete division of the ductus are attended by a certain number of recurrences. Simple ligation with silk wrapping the ligated duct with cellophane in the hope that the fibrosis thus promoted may cause per manent obliteration of the lumen ligation and divi son of the ductus, each has its good points and hazards

Ligation of the duct with cellophane offers the saf est and most efficient method of occlusion. Hence prophylactic ligation of the uncomplicated patent ductus arteriosus by qualified surgeons offers the possibility of a normal life expectancy to many patients who otherwise have little hope of living beyond the age of forty STEPHEN A. ZENKAN M.D.

## ESOPHAGUS AND MEDIASTINUM

McHenry L. C.: Benign Esophages! Strictures. J Oblahems M Ass 945 38 469 Benign esophages! strictures are caused primarily

by cicatricial contracture of the esophageal wall as a result of injury and healing processes. These injuries are caused most frequently by corresive chemicals. at times by foreign bodies, by instrumental trauma, by ulceration from severe infections such as typhoid fever and by peptic picer Household lye, which is composed of 95 per cent sodium hydroxide, is by far the most common causative agent. Small children attempt to drink such solution or find the dry pow der and mistake it for sugar Adults at times ingest these caustive substances by mustaking them for some medicament and at times attempt surride by purposeful ingestion. First aid measures such as dulate vinegar or lemon fulce with large amounts of water must be administered very quickly to limit appreciably the extent of the injury. By the time the doctor sees the patient the damage has already been done. Immediate treatment can then be only pullia tive and supportive. Under proper care the patient may get along fairly well for from two weeks to two months when swallowing becomes more difficult or even impossible because of secondary closure of the exophageal lumen. The ulcerations may be healing and the closure be caused by fibroals and contracture Secondary infection may have caused increased swelling granulations, and even further extension of the tissue damage. This will of course, eventually result in more extensive fibrosis as healing occurs.

Treatment must be directed first toward preserving the life of the patient, second toward maintain ing hig seneral state of beath so that he may heat his lesions, third toward maintaining a patent esopha goal lumen and last toward restoring this lumen to a succompatible with relatively normal esophageal.

function.

If the patient is in shock he must be treated generally for shock as in any serious injury. Furenteral fluids are usually necessary to maintain fluid belance and prevent acidons. If there is definite laryngeal obstruction tracheotomy may be necessary. The use of gentle mechanical suction to remove produce a cretions from the mouth and threat is very helpful Keeping the mouth clean not only makes the patient more comfortable but helps prevent stagnation of infected mouth secretions. Heasures such as pencillan and the sulfonamides to prevent secondary infection are of definite value. If the patient does not begin to swallow liquids within a very few days the performance of a guistrostomy will make possible.

If the patient can be persuaded to swallow a thread and to let the thread remain in place he will

the maintenance of nutrition.

never develop complete occlusion of his explore. Attempts to keep the enoplayed lumen open by it use of catheters, Levine tubes, or bouges dong stage of acute ulceration are at times recognition at they are dangerous and add an element of turns to the pathology already present.

Estimation of the degree of damage to the cookgas and of the extent of healing is made by any study and by esophageocopy. The latter must be done very cautionally and usually only the moproximal portion of the involved area can be visualized.

Once the ulcerations are healed or nearly healed, the problem of obtaining and maintaining an air quate esophageal lumen must be considered.

Dilatation of the strictured esopharus is obtained by passing bougies through the exophagus is gud ually increasing sizes. Eventually almost all care can be restored to practical function. Except to very mild injuries a lumen of normal size and fed bility is rarely attained. There are several methods of dilatation commonly used. The most easily used is sample peroral passage of bougges made for the h the exophagus It is rightly called blind bouguage in that the operator cannot see that the boure is engaged in the lumen of the stricture. There are ally a dilated area above the stricture and the s often sacculated with the small lumen lying on the side wall of the sacculation. A blindly meeted bouge is apt to implage on the thin wall of the sacrelation rather than enter the lumen and if an appreciable amount of force is used perforation will resid. This method is the least effective and the most disgerous of any under consideration. Peroral passes of bouges through an esophagoscope is used a clinics where facilities and trained personnel are available to perform frequent esophagoscopies. method used almost entirely in several excelest clinics is the passage of bougles over a string which the patient has swallowed. If sufficient strug s swallowed to pass well into the small intestment may be drawn sufficiently taut so that a book passed downward over it will be certain to engur in the lumen of whatever passage is present through the esophagus. The fourth method of dilatation was devised by Gabriel Tucker and is known in retrograde bouginage it necessitates a large gastrotomy The patient wears the string continually ore end being brought out through the abdominal and the other through the nose and the ends bed

The authors have studied the records of 51 pttients who have suffered burns of the crophages. There were no patients under 1 year of age Over one-half of the patients were 3 years of age or Gastrostomies were performed upon 38 younger crasted by direct bouginage only Usu ally the bougle was passed through a larry goscope or coppagoscope with visualization of the proximal stricture. Frequently, after initial visualization of the stricture simple blind bouginage was employed Seventeen patients were treated by retrograde dilata Eleven patients were treated by both tions only Eleven patients were treated of the series had no dilatations methods Many of the patients are treated over long periods of time the average for the series being just over forty months The longest period of treatment was eleven years Eleven patients, just over 17 per cent of the series died from various causes while under observation Eight patients 153, per cent died of perforation of the exophagus by bouges Four of these were perforated on the first attempt to get a houge through their esophagus. The authors be lieve that at least a portion of this mortality might have been prevented if early gastrostomies had been done and no attempt made to dilate the csophagus until healing of the ulcerations had taken place

Approximately 75 per cent of the patients are eventually relieved of their obstructive symptoms They lead normal lives and except that they must be very careful to masticale their food thoroughly

Abbott, O. A. Abnormal Esophageal Communications Their Types, Diagnosis and Therapy get along very well. J Thorse Surg 1945 14 382

Abnormal acquired fistulous communications may occur from the esophagus into the bronchial tree pleural cavity mediastinum pericardium, and more remote tissue spaces. The etiology of such conditions depends upon the same factors which may cause fistulas elsewhere namely malignant tumors in flammatory diseases trauma and possibly predisposing congenital abnormalities Carcinoma of the ecophagus and bronchial tree, and malignancies of neighboring structures such as the thyroid and mediastinal glands constitute the most frequent cause of esophageal fistula formation. A fistula may develop in conjunction with an esophageal diver ticulum. Such a diverticulum is most likely to be of the traction or acquired type so that the diver tienium itself plays a secondary rôle in the actual ethology The types of traums which are found reported include gunshot wounds the ingestion of sharp objects crushing injury to the chest, penetra tion by bone fragments and surgical procedures such as bouge dilatation esophagoscopy and anas-

An exophageal fistula presents a serious hazard to the patient a life but not necessarily a hopeless one The author's report adds 6 permanent closures to the 15 previously recorded. Two unusual cases of esopha gopericardial fistulas are included in the reports Another case in which a fistula between the csopha gus and the traches occurred in association with

Hodgkin a disease is described and in this the com munication was successfully treated

The history of choking paroxysms on the ingestion of fluids is the most dramatic and suggestive diag nostic symptom especially when it occurs in rela tion to fluids rather than solids The latter may easily slip past a relatively small aperture Dys phagia is a frequent precursor of the complication The patient may describe the ability to swallow fluids without discomfort when in certain positions The disgnostic measure of greatest value consists of x ray visualization of the fistula preferably with lodized oil to prevent benum irritation of the lung countered in trying to visualize these communica tions directly with the aid of the esophagoscope but the instillation of methylene blue within the csopha gcal lumen followed by bronchoscopic examination can be a helpful measure. In cases wherein the fis tula empties into the pleural cavity or through this route to the body surface one should look for the presence of food particles yeast cells or the appear

The fundamentals of therapy are first, the main ance of ingested dyes tenance of nutrition and second appropriate drain age Many fistulas will disappear apontaneously under this management provided the chology is non cancerous Specific local therapy may consist of topical applications or a direct surgical approach. The question of when to resort to usual nesal tube feedings and when to resort to gastrostomy may be a vital one It would appear that a primar, trial on nasal tube nutrition is indicated in all instances if a tube can be passed From the frequency with which coughing paroxysms may be initiated on each gastrostomy feeding the advisability of jejunostomy is suggested as a preferable procedure in some cases This is more mandatory when the lesion is low in the csophagus or at an csophagogratric anastomosis

In view of the 1 successful result noted and 4 others mentioned in the literature topical applica tion of a strong cautering agent should be given a trial in esophagobronchial fistulas not accordary to malignancy Should all other measures fall and sur gery appear to be indicated, then jejunostomy should be instituted along with satisfactory thorn cotomy drainage at the time of repair In lesions secondary to tuberculosis the outlook is extremely poor In view of the secondary invading organisms, open drainage appears mandatory and this should be done anteriorly to allow subsequent thoracoplastic measures as a means of fistula closure. Furthermore in consequence of the chronicity of these lesions gastrostomy or jejunostomy should be an early con

Boros, E.; Carcinoms of the Eaophagus. A Survey of 332 Cases. Gastroralersloty 1945 5 106

Carcinoma of the esophagus is one of the most common of all malignant diseases. The tumor is invariably primary and is most frequently found in the male perhaps because of the greater use of alcohol, and tobacco. It is a brease of midble at though cases of persons aged 19 as well as 90 have been reported

Analysis of the types of cells constituting the tumor showed them to be squamous carcinomas (78%) adenocarcinomas, and undifferentiated car cinomas. On gross examination the tumor can be differentiated into scirrhous, medullary and papil

lary types.

Unfortunately subjective as well as physical evi dence of the presence of an esophageal tumor does not become manifest early. The symptoms are obscure until considerable growth has occurred and loss of weight and strength are little manifestations. Obstructive features often bring to light the nature of the silent process. Glands in the neck may be the first signs, and esophagoscopy should be performed when a doubt exists, but unfortunately the results of the examination are not always satisfactory

The most prominent symptoms in the order of frequency are dysphagia pain weight loss vomit ing hoarseness bleeding and coughing

While the outlook for the patient with esophageal carcinoma is practically hopeless impetus in the direction of surgical management has been forthcoming Boros summarises the operative treatment of 7 patients on whom a total extirpation was at tempted. The lesions, however were found to be inoperable. Gastrostomy was performed on another group of 168 patients, whose subjective complaints such as swallowing were relieved but no prolonga tion of life was obtained. The mortality was 25 per cent, and it was questionable how much real benefit was obtained from the operation.

Dilatation of the narrowed esophageal lumen has given satisfaction, and its mortality is low Dilata tion with the Plummer dilator accomplishes the desired end of enabling the patient to eat and carries

little attendant risk.

Among the 80 patients subjected to intensive radiation therapy in this series only occasional improve ment in deglutition was observed. The improve ment however was not sufficient to warrant the inference that such could be expected with any measure of certainty as a consequence of the treat ment. For the most part there was but little gross change, and the tumor mass showed no signs of shrinkage when compared with the esophagoscopic observations made before treatment. On the contrary congestion and edema became more pronounced. The length of life of the patient after radi ation therapy ranged from 1 to 11 months.

In spite of everything so far devued, carcinoma of the esophagus is practically always fatal and the results of surgery have been almost uniformly had STEPHER A. ZIEMAR M.D.

Norris, T St.M : Through-and Through Bullet Wounds of the Mediastinum with Recovery Laucet Lond., 945 \$49 464

Three cases of through and through bullet wounds of the mediastinum are presented from a series of 11

penetrating wounds of the chest. One of the tr patients died but not 1 case of bemotherax because infected It is interesting to note that all of the cases except 1 were seen within a few hours of injun

Case 1 presented a through-and-through bale wound of the chest. Serum was given by latteress drip On the seventh day a roentgenogram of the chest showed a right hemothorax and a hemore cardium. Aspiration of the perfounding was performed and only a small quantity of partially dotted blood was obtained. The patient was out of below the twelfth day. He was evacuated on the tweetfifth day Three weeks after the injury a roestgragram showed the heart shadow to be normal and the lung fields clear

Case 2 presented 2 through-and-through billet wounds of the chest. The patient s general condition was grave. A blood transfesson was given Esamination revealed a right hemotherax. A needs was passed into the right chest on the eleventh by and to ounces of sterile fluid blood were assested Fifteen ounces of sterile fluid were aspirated on the fourteenth day. The patient was evacuated on the seventeenth day. Two months after minry it an reported that the patient's right lung had expanded fully

In case 3 the patient had been wounded ; days previously He had hemoptysis and had been great sulfonsmides by mouth. He had a throughted through bullet wound of the chest. There was a large right hemothorax which was aspirated. Thecaltures were sterile. He was evacuated 16 days lowing injury and o days after admission to the hospitel

These cases were treated conservatively When intrathoracle hemorrhage occurred the patients were not operated on for at least a week. The patients were not moved during the first 48 hours, being left in bed in the clothes in which they arrived. They were given sufficient morphine to make them epthetic during this period. Fluids were given liberals by mouth Penkeillin was given Intrammenlarly so ooo units every three hours. When operation of a hemothorax was carried out, 40 000 units of penicha in so c.c. of saline solution were injected into the pleural cavity Only small amounts of intravenous therapy were given.

RICHARD J BESTRETT, J M.D.

Humphreys, G. H., and Southworth, H.: Aphale Anemia Terminated by Removal of a Mednational Tumor Am J M Se, 1945 1 0 pm

With the exception of tumors of aberrant panthyroid tissue and those arising from the thymse there are no known mediastinal tumors hick in general effects. Only a few tumors apparently as sociated with anemia, because they influence either the formation or the destruction of blood, last been reported.

The 58 year old patient in the case reported by the authors had a mediestinal tumor which had been present for a number of years it had resisted rade therapy but showed no signs of malignancy Dur ing a considerable period of observation the patient nifiered from a profound depression of erythrocyte formation, although leucocytes of bone marrow on gn were never deficient in number. The red cells present were not abnormal in size or shape, and there was no evidence at any time of chronic blood loss or abnormal erythrocyte destruction During this pen od of anemia, reticulocytes were never found on any attempt except twice when isolated ones were seen within 48 hours of large transfusions. All of the usual therapeutic measures to stimulate red cell lormation were without effect. The patient was maintained with transfusions of whole blood and saline suspensions of erythrocytes for 22 months The mediatinal tumor was removed without diffi culty and the patient made an uncomplicated re-

Following removal of the tumor a sharp reticulocytosh occurred with a resultant restoration of the erythrocyte count to normal, where it remained for a year after operation During this period the pa tient acted on one occasion as a donor for a transfunou, following which her reticulocytes responded normally and her blood count was not conspicuously affected Ten months after operation she developed an abscess in the thigh which required drainage and an autocoo in the ringu winch required the makes and healed slowly. A year after operation before the astocas had bealed completely the patient rather suddenly developed acute ascites and jaundice went to be a suddenly developed acute ascites and jaundice went to be a suddenly developed acute ascites and jaundice went to be a suddenly developed acute ascites and jaundice went to be a suddenly developed acute ascites and jaundice went to be a suddenly developed acute as the into come and died Autopsy showed widespread bemochromatosis and no evidence of reappearance of the original tumor The nature of this tumor remains in doubt, although a thymic origin was sug gested

# MISCELLANEOUS

amson, P. C., Burbank, B., Brewer, L. A. III and Burford, T. II. i Immediate Care of the Wound ed Thorax J Am. M Ass 1945 129 606.

A rational plan has been adopted for the early preoperative care of the severe thoracic casualty which program is applicable to the thoracic injuries and wounds which may be encountered in civil and

Adequate resuscitation is a necessary preparation for surgery or for transportation Unless hemorrhage industrial practice. or the urgency of other wounds dictates early surgi cal intervention the majority of serious thoracie casualties will be greatly benefited if they are not mished to the operating tables, because patients with extensive contusions of the lungs or heart are poor raks and surgery in these patients should be de

The methods of resuscitation are (1) restoration layed whenever possible. of normal thoracic physiological conditions including the control of pain and the treatment of hemothoray anoxia, and pressure pneumothorax (2) fluid re placement and (3) the early prevention of infection Oxygen should be freely used before syanosis develops in any patient who is restless or dyspneic

or whose pulse remains elevated (aution should be observed in the administration of morphine proving thoracic dyafunction consists of nerve block for the control of pain, thoracentesis and water trap catheter drainage for intrapleural pathological changes, and mechanical suction (eatheter aspira tion bronchoscopy) for the removal of excessive bronchial fluids.

# Berk, M : Cardioesophageal Relaxation Gariro-

Cardioesophageal relaxation or incompeniency of the cardiac sphincter is an abnormality in which contents from the stomach regurgitate freely and passively into the esophagus and may be looked upon as a direct antithesis of achalasia (cardiospasm) Although it can be recognized by means of x rays, and though in itself is apparently not a clinical entity, it nevertheless assumes importance in its differentiation from other conditions occurring in the terminal esophagus. It frequently gives rise to symptomatology distressing enough to require

In patients observed by Robins and Jankelson the lower I to 3 inches of the esophagus was found to be medical attention. dilated These authors classified the dilatation into two types tubular and globular according to the degree of reflux, its duration and possibly on the gastric tone or intragastric pressure. They divided their cases into three groups according to the im portance of the condition (1) those with demonstra ble gross pathological changes within the gastroin testinal tract, (2) those with pathological changes outside of the gastrointeaunal tract, and (3) those with only functional disturbances. The third group was termed pure cases of cardiocsophageal relaxa tion. All of the patients were considered unstable being classed as psychoneurouc. In general this group was characterized by hypochlorhydra, and the x rays revealed hypertonicity of the stomach with moderate pylorospasm To reverse peristalsis

Two theories as to the explanation of the phe nomenon of cardiocsophageal relaxation may ex plain the reflux of barrum into the esophagus First there is an increase in intrapastric pressure due to hypertonicity or hyperperistains with equal pressure on both openings. The weaker or cardiac sphincter will give way with reflux of the gastric contents into the esophagus. When the tension is relieved the liquid reflux will return to the stomach sided by esophageal peristalsis and its own weight. The sec ond theory has to do with a disturbance in balance

The author reports the case of a 47 year old male of the autonomic nervous system who gave a history of stomach trouble since 1917 and complained of epigastric dutress. The patients complaints consisted of intermittent episodes of full companies consisted in meaninteen epissues of the test state meals, belching pyrosis, nauser regurginess after meals, belching pyrosis, nauser regurginess and rare voniting. He complained of no true abdominal pain Relief from his symptoms would be a supplied to the belching test of the particular come principally from belching regurgitation of small amounts of liquid food, and the use of alka seltzer Most important of all, he found that when he took the upright position and walked around he would nearly always obtain relef. In addition he began to note during the past few years that when he ate solid foods he would frequently have the sen sation that they had been obstructed at the region of the lower sternum.

Cholecystograms gastromtestinal series and fluor oscopic observations revealed no gross pathology to be present. Films taken in the recumbent position presented a globular mass of barium just above the cardia in the region of the lower esophagus. In the supine and Trendelenburg positions a portion of the barium was seen to roll back into the esophagus and extend as high as the upper third of the latter In addition, baruum was observed to pass to and fro within the esophagus, according to the phase of respiration. When the patient was placed upright the meal was seen to flow back into the stomach.

An esophagoscopic examination revealed that the esophagus was dilated and flabby. Without meeting the least resistance the instrument could be propelled forward into the stomach. There was no true histus hernia.

A diagnosis of cardocosphageal relaxation was made. An attempt was therefore carried out to stimulate the smooth muscle tone by the use of physostigmine and prostigmine given both orally and parenterally, without any apparent benefit. Ad ditional drugs which proved ineffective, were dilute hydrochloric antacids and belladonns. The regimen which seemed most beneficial was to have the patient eat a light meal several hours before bedtime and remain erect during that time.

The importance of cardioesophageal relaxation is its possible confusion with other more significant leations occurring about the terminal esophagus. In fluoroscopic examination, particularly in the erect position, the csophagus appears normal in all respects, except possibly for the normal lack of delay at the epicardis. If fluoroscopic examination is negative in the erect position and a globular or tubular shadow of barium is seen just above the stomach on the immediate films in the supuse portion, cardioesophageal relaxation should be suspected

LLE PULLEY M.D.

Paine, J. R., and Piankera, A. G. A Roriew of Patients with Intrathoracic Disease and Injury Treated on the Surgical Service of a United States Army General Hospital in North Africa. Surgery 1945, 18 401.

Of 81 patients admitted to the Chest Division of the Surgical Service of a United States Army General Hospital during the period of its operation in North Africa during the spring, summer, and fall of 1043 66 were battle casualties. The hospital installations were in Nissen buts and tents. Until the end of the Tunisian Campaign this hospital was the most forward of any of the American general hospitals in North Africa. Even at the busist periods however the hospital was not called spea to reprimary surgical treatment to any battle erecexcept in a few isolated instances

The report concerns only those patients with r trathoracic disease or injuries involving the thraccavity and there was only 1 death during operator. that of a patient with mediastinal teratorn, Ttreatment of patients with intrapleural access tions of blood or bloody fluid was accomplished by repeated thoracentesis Seventeen patients ladies subjected to primary major surgical procedure more forward hospitals only t however, and treated at this hospital. Twenty-or patient is metallic foreign bodies retained within the chet k. none was operated upon at the hospital, T est is per cent of all patients with intrathorace some r injuries were returned to duty after their stn z the hospital, and one patient with as organic intrapleural hematoma was successfully occurupon with gratifying immediate results.

STEPHEN A. ZIENAN, M.D.

Harrington, S. W. The Surgical Treatment of the More Common Type of Disphragmatic Boss Ann. Surg. 945 22 546

In the author's experience with 441 core diaphragmatic hemia the most common by which require surgical treatment, in order directly of the most common than the most common and the most core trauma, indirect or direct, or to indiamentary recroils absence of a portion of the diaphragmatic pleuroperitonesalis hemis and herois through the foramen of Morgagni.

Each of these various types of daphanets hernia presents different clinical manifestitioned requires different methods of surpical treture. Some of the more important clinical and surpaspects of these different types are considered not

original article. The clinical syndrome of disphragmetic lenmay be divided into two main types. The fix occurs in cases in which the stomach is the acabdominal organ involved in the hernia. The star toms are those of intermittent and usually practisive incarceration and obstruction of the stead The most common type of disphragmatic bens ! which the stomach is the only abdominal viscos of volved is through the esophageal blatus. However, this type of hernia may contain various porters of the omentum, according to the amount of stored involved in the hernia. Insamuch as this tyre progressive the entire stomach may become brok in the hernia, and the colon may also beceme corporated in the hernlal sac because of its studment to the greater curvature of the stomach rarely the spleen may become involved because di attachment to the cardin of the stomach. In cases in which the colon is involved, there may be additional symptoms of partial or complete interest obstruction

obstruction

The second type is found in the case in slidmult ple abdominal viscera are involved in the ernia. The bernia is usually of traumatic origin and s caused by laceration of a normal diaphragm. However it also may be of congenital origin and may result from congenital structural deficiency of may result from Onigential acquering democracy of the disphragm. The symptoms are more varied and severe than those in the first type because of the multiple structures involved and they are often more acute in onset The initial symptoms may be those of acute intestinal or gastric obstruction or

In the treatment of all hermas that have occurred through the left portion of the diaphragm, the author prefers the abdominal approach by means of author process are accommon approach by means of an oblique left rectus incision starting at the ensiform cartilage and extending to the outer border of the rectus muscle. He believes there is less risk of though muous are beneves there is less risk of It is of particular advantage in cases of esophageal hernia for the herniated stomach is usually confined in a sac in the posterior part of the mediastinum

nd does not enter the true pleural cavity In the repair of hemias through the right portion of the duphragm the author prefers the thoracic approach because the large, right lobe of the liver makes the abnormal opening in the diaphragm inac cessible from the abdominal approach.

The technical difficulties of adequate exposure of the hemial openings through the left portion of the

diaphragm and the esophageal hiatus are often con siderable because of fixation of the left lobe of the liver to the leaf of the diaphragm The exposure is greatly facilitated by cutting the suspensory liga ment and retracting the left lobe of the liver to the right. This can be accomplished when the left lobe is small, by folding it on itself, and when it is large by retracting it forward into the wound The spleen is often very adherent to the posterior part of the disphragm and hernial openings, but usually can be separated from these structures by blunt dissection In some instances the spleen has been so traumatized by the injury and so bound into its abnormal posi tion by adhesions that it cannot be separated from the hernial opening without seriously injuring it This not uncommonly occurs in the traumatic types of hemia and occasionally in esophageal histus bernia. In cases of this type splenectomy is nec

Paralysis of the disphragm produced by temporary or permanent interruption of the phrenic nerve, essary is of value as a procedure preliminary to radical operative repair of esophageal hiatus hernias It is a necessary procedure in the surgical treatment of partial thoracic stomach resulting from a congent tally short esophagus In some cases in which radical operative repair is contraindicated it may be used as a palluative measure

## SURGERY OF THE ABDOMEN

## ABDOMINAL WALL AND PERITONEUM

Gatch W D., and Montgomery W F : External Hernias Containing Gangrenous Bowel J Am M Ass 945 199 736.

A review of the reports on strangulated hernia published since rors shows that the results of treat ing this condition are as poor now as they were then in fact the death rate is about as high today as it was in the days of preasentle surgery. The plan of treatment described by the authors briefly consists of three parts

I Incision of the hermal sac together with the gangrenous bowel within it.

2 Deflation of the obstructed bowel with a Miller Abbott tube down to the point where it is obstructed at the hernial ring. This restores it to a healthy condition and permits giving the patient liquids and soft foods by mouth, which corrects starvation and dehydration.

3 Laparotomy done after the tube has been down for about a week (through a low paramedian incision) excision of the gangrenous bowel, and in testinal anastomosas plugging of the femoral ring with omentum statched to it and treatment of the abdominal wound with sulfathlazole after closure of

the peritoneum.

Three case histories are given. EMIL C. ROBITHERE, M.D.

Aird I: Acute Nonspecific Mesenteric Lympha denitis. Brit M J 945 2 680

Although often described in British, American and other medical literature the author believes that acute nonspecific mesenteric lymphadenitis has found no general acceptance as one of the commonest causes of acute abdominal pain in children and as an occasional puzzling affection of adults, As a rule the term is omitted from the index and text not only of surgical manuals but even of encyclopedic reference works, and there are hospitals in which all inflammatory enlargements of abdominal lymphatic glands are presumed to be tuberculous. If the condition is mistaken for acute appendicitis as it frequently is no great harm is done it may be wise to sacrifice accuracy for safety Material injustice may be caused however if the disease is wrongly labelled tuberculosis." the patient's medical record is distorted relatives are subjected to unnecessary anxiety and the premium for a life insurance policy may be raised.

As to the pathological features, the mesenteric glands-juxtaintestinal along the mesenteric attach ment of the lowest few feet of Heum, intermediate along the ileal arteries and terminal on the main superior mesenteric trunk-are discretely enlarged The first or the last of these groups may be involved alone or all three groups may suffer together. The

anterior and posterior cecal and fleocolic glassica or may not be simultaneously affected. The art intestinal glands are predominantly invents early stages of the disease early in an attack for may be pink in color but usually they are local. be white. The intermediate and terminal shows predominantly affected in later stages of the fruit they seem always to be white in color The minglands are soft and julcy at first, clastic kin, in finally quite hard, it is uncertain whether order tion ever occurs in nontuberculous adeath Is leaves of the mesentery, and if the terms leave mesenteric glands are involved the adactive toneum of the posterior abdominal vall, as k congested The perstoneum of the asterior size. nal wall is nearly always unaltered. The lens, = sometimes the cecum and appendix as vel, as show serious hyperemia, and sometimes a princiedema of the whole thickness of the bord of This inflammatory appearance of the interior commonly found only during earlier attacks of its disease it may affect a considerable length of len fleum, or several discrete stretches of bord, a exone short segment or it may be restricted much palpable thickening of Peyer's patches. Frequent, with or without an inflammatory appearance of the bowel there is a small quantity of clear feel in within the peritoneal cavity

The history is not particularly characters to It patients more often male than female, are were children beyond the years of infancy but the on dition has been recorded at 10 months and a ? years of age. The pain is essentially a general dominal colic, often of extreme severity and intense and alarming than the initial colic of speed citis in childhood Between spasms of cole tiers entire freedom from pain. Even during the and attack of pain the patient moves freely about violently sometimes, with a constant character position which would be unusual in sente speed citis. As in appendicitis, when the patient shale given a history of generalized abdominal pass asked to indicate the site of most intense per k points to the right lower quadrant. In control b the patient with acute obstructive appendicts, in ever, he cannot locate the rite of mauman precisely but indicates an fil-defined area of the right side Nausca usually with vomitor, and panies one at least, of the initial attacks. Daniel is exceptional. There has been quite often a rem sore throat or other upper respiratory infection

Cinical examination provides no more area evidence than does the history The patent gr seem little affected except by pain, or may be made and obviously feverish or pale be a selden or me prostrated or ominously motioniess. If takes only in an attack, the temperature is elevated to 10 even substantially higher and on the first day are here is an almost invariable leucocytosis of from 5,000 to 20,000 with 80 per cent or more of granu 5,000 to 20,000 with 60 per cent of more or grand ar cells. As a rule the white count falls again on the cond day-its elevation is quicker higher and orter-lived than in acute appendicitis. A bright id pharyngits is not an unusual concomitant of onspecific mesenteric adentits but neither its onspecine mesencial administration of the second of the se bdominal examination tenderness is elicited in he right line foss, higher and more medial than the ne ngm mac toos of acute appendicitis. The lowest init of tenderness is just below and to the right of the umbilicus. When the terminal (superior mesen neric) glands are widely involved a band of tender aces may be outlined as it extends upwards and to the left towards, and sometimes just beyond the

idline of the epigastrium. The right lower abdomi al muscles are nearly always in slightly higher tone han their fellows of the opposite side but rigidity is not maximal or if it is the muscles soften per eptibly under continued gentle pressure Rebound tenderness is not unusual, particularly if the leaves of the mesentery or the serous of the bowel are in flamed. One sign, shifting tenderness, is said to be pathognomonic certainly its presence is most sug gestive though its absence is not significant elicit shifting tenderness the site of maximum tender

as is located while the patient lies supine the potion is then changed to the left lateral, and after a with a men changed to the left section, and are we minutes, if the sign is present the point of maximum tenderness will be found to have moved left ward to or beyond the midline The sign depends upon postural displacement of the lower fleum with its mesentery, and is elected only if the juxtaepi physical giands are inflamed. Rarely it may be positive early in acute appendicute if the eccum is highly mobile The enlarged glands are seldom pal pable, even those at the root of the mesentery fixed against the background of the posterior abdominal rall and free fluid is not often of sufficient amount

Confusion with appendicates is less likely to occur to be detected by percussion in practice than seems possible when the symptoms and signs of the two conditions are compared on paper The sharp spasms of colic with complete or almost complete freedom from pain between them the rolling and kicking of the child in an attack the high and medial situation of the tenderness, the absence (if it is absent) of the rebound tenderness even at the point of maximum tenderness the presence (if it is present) of shifting tendemess, the relaxation under steady pressure of apparently rigid muscles and the history of previous typical recur rent attacks if these have occurred, all inspire confidence in a negative diagnosmof this is not appendi dis" even if they fall to suggest the positive diag nous of nonspecific mesenteric adentis.

Differentiation of nonspecine from tuberculous mesenteric adentis is not always easy. In the latter condition leucocytosis is usually absent throughout the abdominal wall is almost completely lax, en larged matted glands are usually palpable and pain

or at least discomfort is more constant between attacks. If operation is not performed and doubt exists, it is not only more accurate but it serves better the interest of patient and of community to regard the condition as nonspecific unless there is dear evidence of tuberculosis elsewhere—in neck or

Other forms of mesentene gland enlargement chest, for example seldom produce acute abdominal symptoms. At operation malignant glands can usually be recog nized by their character. In lymphadenoma and

infectious mononucleosis glands elsewhere in the body are simultaneously enlarged Even so it is wise in nonspecific admitts to carry out a differential white count and the Paul Bunnell test

The appearance in the glands, and more especially the appearances (when they are present) in the wall of the intestine are those of acute inflammation and strongly auggest a response to infection The appendicular origin of nonspecific adenitis however, is difficult to substantiate when it is remembered that the juxtaileal glands predominantly and in variably enlarged in the early case of adenlits are not found enlarged at operations for overt appen

Nonspecific adenitis has been ascribed to the passage of a hypothetical virus through the mucosa of dicular infections the intestine to its submucous lymphatic tissue, and thence to the mesenteric glands Some support is lent to this hypothesis by the failure to culture bac teria from glands which are apparently the seat of acute inflammation The coincidence or precedence of upper respiratory tract infection is an additional argument in favor of a more or less generalized virus A relationship might be suggested between mesentene lymphadenitis and the scute regional ileitis of Crohn. The gland enlargement in the mesentery of the affected bowel in regional ileits is identical with that seen in nonspecific mesenteric adentis indeed it is a nonspecific meenteric adentis conversely an early nonspecific adentis accompanied by a patchy pink inflammation of the serous coat of Heum and more significantly still, by an edema of all coats sharply demarcated from healthy bowel suggests an early, mild, self limiting regional ilelia it is a regional ilelia in the widest sense of the term The identity or diversity of the two conditions could be proved only by the demon stration of the ultimate cause of one of them or the

In the author's experience appendectomy does not affect the course of the disease which in any case causes of both is self limiting and from which ultimate recovery seems to be invariable.

# GASTROINTESTINAL TRACT

Hardt, L. L., Hufford A. R., and Rabens J I. An Analytical Surrey of 1132 Patients Gastro-Scopically Examined, Gestroenisrology 1945 4 477

One or more gastroscopic and roentgenological examinations were performed on 1 132 Patients who eosin. One block was me is through the anast motic junction extending through the ulcer and the other section from the anastomotic ring free of gross ulceration.

In this study the gastrojejunal ulcer was found to be a disease of middle age 93 per cent of the patients were men and 7 per cent were women. Pain was the most common symptom of gastrojejunal ulcer in this series of patients, being present in 85 per cent of the patients. The location of the pain varied markedly in some patients the pain was epigastric or the same as that produced by the original duodenal ulcer in others the pain extended downward to either side of the umbilicus or upward to the shoulder blades at times the pain extended downward as far as the

groin.

Hemorrhage was the most common symptom.

Hematemesis and melena occurred in 32 per cent of
the patients and melena alone in 42 per cent. The
hemorrhages varied from massive angle hemorrhages
to repeated small hemorrhages. Vomiting occurred

in 24 per cent of the cases.

Histological examination in this series showed that 87 per cent of the ulcers were on the fejunal side of the anastomosis, 3 per cent on the gratric side, and 3 per cent on the anastomotic line. The site of the

remaining 13 per cent could not be determined. In general, the ulcers resembled the peptic ulcers customarily seen. They were typically rounded and stamped ut the mucosa and submucosa were absent over the base of the ulcer, and the muscular layers were completely replaced by fibrous tissue. Scrosz was absent in all instances. It was concluded, however that the absence of scross was secondary in importance to the method of preparation of the alide The anastomotic junction showed that the mucosa was well united in most instances but varied somewhat from the normal. Usually the gastric and fejunal mucosa ended abruptly but there were instances in which the jejunal glands were seen o the gastric side of the anastomosis. In a similar fashion gastric glands with acid cells were seen as frequently on the jejunal side of the anastomosis.

In the majority of cases a moderate degree of both gastrilis and jejunitis was noticed An attempt was made to correlate the severity of the clinical symptoms with the pathological changes, but relationably was evident. In some cases of severe gastrocipluitis only mild symptoms occurred whereas, on the other hand, in some cases of mild gastrojejunitisthe clinical symptoms were severe.

SAMUEL J FOOTLISON M.D.

Ransom, H. K. Gastrojejunocolic Fietula. Sur gery 945 18 177

During the 10 year period from 1934 to 1944 47 patients were treated by surgical operation for mar giand or jejunal user at the University of Michigan Hospital, Ann Arbor Five of these 47 patients required an additional operation during the same period because of recurrent gastrojejunal ukcration and 1 patient was operated upon three times for

tl is same a ndition. Thus, a total of 54 operations was performed upon 47 patients. Of the afore mentioned 47 patients, 8 (17%) had the senous complication of gastrojenucoolic fatula. It is with this latter group of cases that the present discussion is concerned.

A survey was made of all of the cases of gastolejanocolic fistula at the University Hospital since its opening in 1925 and it was found that during 1925 to 1944, 18 unmistakable cases of gastrolejunocolic fistula due to ulcer had been encountered.

Gastrojejunocolic fistula almost invariably ocran as a complication of a marginal or jejunal ulcer at the site of a gustroenteric anastomosis for duodenal ulcer The great majority of cases occur in mstances of posterior gastrojejunostomy and much more often following simple short circuit operations rather than in cases of gastrole unostomy associated with partial gastric resection. In every one of the cases under discussion, duodenal ulcer was the primary lesion. It is a well accepted fact that marginal ulcer rarely occurs following gastroenterostomy for gastric ulcer and is almost unbeard of following gastroenterostomy for carcinoma of the stomach It is often stated that gastrojejunocolic fistula and gastrojejunal ulcer very rarely occur in women, the reason for this being the lower values for gastre acidity in women as compared with men. Walle the exact cause of marginal or jejunal ulcer is not known, the prevailing view is that these lessons most often occur in patients whose gastric acidity remains high following operation. This is much more apt to be true in gastroenterostomy or duodenal exclusion operations as contrasted with subtotal gastrectomy In all of the authors cases, save 1 posterior gastroenterostomy was the primary operation which as

followed later by a marginal ulcer.

It would be expected that prior to the onset of the fistula, symptoms of an anastomotic alcer would usually be present. This, however was not true in the majority of the cases herein reported as only for emailing 1 a patients in this sense apparently were relatively symptom free until the onset of the symptoms of instula. In view of the mechanical nature of the lesion any great improvement in the state of nutrition prior to operation is difficult 1 impossible. Properative laboratory work should include the determination of serum proteins and prothrosian cotting time.

The surgical operation in all cases consisted of a one stage procedure. In 10 instances a restorative type of operation was performed wreets in 4 case, gastric resection was included. There was 1 port operative death in each group, ra mortality of 113 per cent for the entire series.

Follow up studies showed that all patients who survived operations including gastne resection had good results, whereas only 4 of the 9 patients or viving the more conservative operative procedure remained free of ulcer symptoms. Three of the 5 patients with recurrent ulcer subsequently required patients with recurrent ulcer subsequently required.

further surgical theral 3  $N_C$  leaths occurred any  $n_C$ these patients who later required reoperation

While gastric resection is ordinarily desirable at the time of the operation for the repair of the instillars, it is not always feasible or safe Restoration of the tract to normal, therefore is a useful procedure in certain cases This was true particularly in these cases because many of the original gastroenterostomics were performed upon meager indications as judged by present day standards. If further surgery junged by present the ulcer becomes necessary later for recurrence of the ulcer becomes necessary later subtotal gastrectomy can be carried out upon a patient in good condition with a very low mortality

Gastrocolic fistulas due to primary disease of the stomach or colon are discussed The petients present problems in preoperative care and in certain matters of surgical technique which are similar to

A small group of gastroenteric fistulas due to sur those just discussed goal errors at the time of the original operation for ulcer is considered briefly

# Berkman J M., and Heck, F J : Symptoms fol lowing Partial Gastric Resection Gentrocaler

The authors present a resume of their observations of the unfavorable symptoms exclusive of recurrent ulceration which may follow partial gastric resec tion The cause of these symptoms has not as yet been explained satisfactorily At the present time however the most commonly accepted explanation of the postprandial symptoms known as the dump-

ing syndrome, is jejunal distention The manition which may occur as a result of the postprandial symptoms may be overcome by placing the patient on a high protein diet, first with a small amount of bulk and then a gradual increase of the bulk to that amount represented by 2 500 calories. By this method without further increase of bulk, a diet with a calone value of 3 200 calories may be reached which will insure a progressive increase in weight without an increase of the seventy of the

A group of patients who have experienced nauses postprandial symptoms. to a sufficient degree to prevent the cating of several nonconsecutive meals each week has been observed The nausea was not associated with postprandial symptoms and did not follow the taking of food

Also a number of patients have been seen who although they had experienced no symptoms after partial gastric resection had found it impossible to eat enough in the usual three daily meals to regain the weight lost after operation. By the dectary method described a progressive gain in weight was brught about without postprandial discomfort.

In some cases hypochromic microcytic anemia developed after partial gastric resection and failed to respond to the usual treatment for hypochromic anemia. The value for hemoglobin improved after a high protein diet with a caloric value of \$ 200 calories

ha I produced an increase in weight CHARLES B ROY M D

Learner N Robinson II W. Grishelmer L M. and Oppenheimer, M. J.: Effects upon the Small Intestine of Rapid Intravenous Injec. commit sincularity of responsion for Carrocalerology

The possibility that amino acids when used intra venously may alter intestinal motility and hence endanger new suture lines prompted the authors emanger new auture miss prompted the auture study. The reaction of the mixture of acids used is in the region of pH 5 and may produce a temporary lowering of the blood pH when introduced into the blood stream in sufficient quantities at a rapid rate The role of change in pH on motility is also in need of investigation and the authors study includes of investigation and the duodenum was selected such considerations. because of the frequency of surgical intervention in this area Studies were carried out on patients with normal geatrointestinal tracts and on dogs with and

The authors discuss the methods used and the results obtained in (1) anesthetized dogs (2) patients without anesthesia with normal gastrointestinal tracts and (3) dogs

In conclusion the authors state that rapid intra recently operated upon venous injections of casein hydrolysate produce a duodenal hypermotility or change in pattern of motility in anesthetized dogs. This hypermotility is not accompanied by significant changes in pil carbon diaxide chlorine or total base concentration of the blood plasma The blood glucose concen Neither hypermotility nor of the blood plasma hypersycemia is prevented by atropine of vagot one. New intestinal suture lines are not disturbed tration is elevated by the hypermotility during parenteral use of casein digest Rapid intravenous injections of casein digest in unanesthetized humans change the character of contractions and often accentuate tonus changes. Subjective sensations and changes in motility were correlated in only half of the cases studied EMIL C. ROBITSHEE M D

# Falk, H. C., and Hochman S.: Intestinal Injury and Fecal Fistula in Gynecological Surgery

The small or large intestine may be injured dur ing any gynecological laparotomy most often on the separation of adhesions found between the intestines, the pelvic viscers and the abdominal wall These adhesions may be the result of pelvic inflammatory disease or of previous operations. This is shown by the high incidence of fecal fiatules following surgery

There were 42 cases of intestinal injury observed for pelvic inflammatory disease. by the Gynecological Service of the Hartem Hos pital from 1918 to 1943 where more than 80 per cent of the patients operated upon have some de gree of pelvic inflammatory disease. During this period of 10 years 5 055 laparotomics were per formed. The known incidence of intestinal injury

The intestines may be injured on opening the was therefore o 83 per cent peritoneal cavity This type of injury as a rule t

detected and repaired immediately. Such accidents are more common in patients who have had a previous laparotomy. In this series there was only it such case. No fatula followed. The bowle may also be lacerated in cutting across the vagina in a total hysterectomy if the rectum is adherent to the posterior wall of the cervix. There was no such accident in this series alongly to the intestines may also occur in the separation of adhesions between two loops of bowel the intestines and pelvic organs, or between the intestines and the abdominal wall.

Two types of adhesions are found, those caused by a previous langratumy in which the intestines and omentum may be firmly matted together with the pelvic organs and those caused by pelvic inflammatory disease, conorrhea produces few adhe sions except at the imbriated end of the tube. The adhesions between the intestines and the tubal wall are usually friable thin and flimsy and easily separated. When the ous has spilled into the cul-de sac, the adhesions between the sigmoid tube, and posterior wall of the broad ligament are very dense. Here the separation is usually done blindly (without vision) and the large bowel may early be injured such an injury may not be recognized. There were 7 such cases of injury in which the algracid was densely adherent to a tubo-ovarian abscess or pyotalpinz.

Usually the intestinal injury is seen and recognized at the time of operation. There were, however many cases in which the intestinal transma ultimately caused necrosis of the bowel, but no injury had been recognized at the time of operation. As a result, a fecal furtual or fatal peritorities courted next

operatively

In pelvic inflammatory disease of progenic or tuberculous origin, degenerated or infected fibroids, endometriosis, ovarian and tubo-ovarian abscesses and malignancies the adhesions encountered are very dense. In the separation of these adhesions to isolate the pelvic structures, the intestines are easily injured

The most reliable index of acuteness of pelvic inflammatory disease is the sedimentation rate

Among the 18 cases of fecal fistula, there were only
4 in which the sedimentation rate was longer than
30 minutes.

30 minutes.

The 42 cases of intestinal injury were divided as

follows
1 Injury detected and repaired during operation without fecal fistula formation—22 cases.

- 2 Injury detected and repaired at operation, with the development of fecal fittula -3 cases.
- 3 Injury not detected at operation, with result ing fecal fistula-15 cases.
- 4. Injury not detected at operation, with result ing peritonitis and death-s cases.
- x and x Injury detected and repaired during operation—25 cases. In 25 or 50.5 per cent, of the total number of 42 cases, injury to the intestines was detected and repair was accomplished during operation.

The prognosis in intestinal injury is largely dependent upon recognition and repair at time of operation

Repair of intestinal injuries was accomplained by two to three rows of locked interrupted, or continuous running sutures of No co chromic cates of Pagenstecher thread.

In recent years 10 gm. of a sulforaunde were placed into the pelvis and over the repaired are.

The treatment of feed fastules low in the interinal ract, as in the terminal fleum, signoid, or remain a much less urgent than that of those located in the duodenum or upper jejunum because of the significant fleum and the significant fleum smally hell spots and for the significant time should be allowed for the factorial state of the significant time should be allowed for the fattulas to chose spontaneously before surgery is attempted. Honey W Fras, Lib.

Pugh, H. L.: Regional Enteritie. Aux. Sury 1915, 127-825

Crohn, Ginzburg, and Oppenheimer in 1813 published the original article describing the climal entity known as regional enteritis. This article was so accurate that all the literature contributing to the subject in the past 13 years has subtracted nothing from it. The original title was Terminal Beks' The author has substituted the word regional since "terminal suggested agonal and enterits les been substituted for "lieitis" since not infrequent other parts of the small or large bowel have been affected. Numerous names have been suggested for this condition, among which have been termina ileitis regional ileitis, regional ileocolitis, regunti enterocolitis, segmental enteritis, nonspecific grass loma, infective granuloma, chronic cicatrising or teritis pseudocancer Crohn a disease, and reposit enteritis. The last mentioned term is the most pops-

lar and comes nearest to being true and appropriate.

The authors present a series of 17 cases, and confirm some of the special observations which have

been made by a variety of contributors.

It is believed that this disease has existed as centuries. W J Mayo in 1893 Combe in 191, and Moschowitz in 1933 described case in the iterature which probably were regional enterlits. Ther appears to be a definite locrease in the incidence of the disease which cannot be entirely explained by

the improvement in dagnosis.
The ctiology of this condition is still unknown.
The theory that Koch s bacillus may be the caretive agent has been disproved. It is not improbable
that there may be some correlation with measures
lymphademitis. An allergic tieup is still fascidSeveral writers have reported that the mainly issue.

a predilection for Jews, particularly at an early at.

It has been claimed that the discret is more perlent in Eastern cities, and it is probable that ther
may be a seasonal variation in the endeaty is
acute exacerbation of the discrete. Croin suggest
the disease may have a familial tendency. It
discuss is more likely to appear between the area

15 and 40 and the majority of statistical reports indicate a slightly greater frequency in males than

Knowledge of the early stage of regional enterities remains conjectural, since it is seldom recognized females. until thoroughly advanced It probably begins as a proliferative process in the interstitial structure of the bowel wall and progresses to a cicatrising granu line nowed wan and programmes becomes ulcerated as long tous lexion. The mucosa becomes ulcerated as the bowel thickens possibly from interference with the blood supply, or from an infective process (virus or bacterial). Fibrosis develops and the bowel wall thickens. This, plus the contraction of cicatrising alcerated areas, narrows the lumen until obstruction may eventuate. The adjacent mesentery becomes

thickened and the mesenteric lymph nodes become enlarged and discrete Both the bowel and the mesentery become edematous With progress of the son the ulcrated areas may perforate and lead statement of the perforation of the second of the seco ommunicate with loops of small bowel, large bowel, hadder, or even through the abdominal wall. Some writers believe that the disease passes through four stages, namely (1) acute, (2) urritative (3) obstruct

Almost any part of the intestinal tract from the ive, and (4) fistulous. rejunum to the algmoud may be involved, with the terminal lleum the favorite site. The disease not m-Irequently extends past the ileocecal junction and invides the occum. Skip areas in several portions of the bowel in the same person may be involved

with healthy segments intervening The disease is chronic and is characterized by periods of exacerbation and remission. The weight of evidence and opinion indicates that spontaneous

The involved bowel during acute stages of the cure, if it ever occurs is rare. decase is swollen hyperenic, and inflamed The mesentery is awollen edematous, and likewise inflamed with lymph nodes varying in size from that of a pea to a walnut. Gross corrugations extend from the mesenteric border and tend to encircle the bowel and give it a cobblestone appearance It is not uncommon to see a considerable accumulation of serosanguineous fluid within the peritoneal cavity during the acute phase. The involved bowel by contrast during the quiescent or remission stage, remains heavy thickened and leathery devoid of its normal flexibility and distendability hyperema subsides the plastic exudate organizes

and forms dense fibrous bands and adhesions. Histologically the affected bowel reveals a marked firming and thickening of mucosal and submucosal layers. The entire structure of the bowel wall shows a mononuclear infiltration. Giant cells are not un common and frequently lead to a false diagnosis of

The symptoms depend on the stage, location and severity of the disease. The three cardinal symptoms tuberculosis. are intermittent cramplife abdominal pain inter mittent darrhes and loss of weight ausea is not uncommon and when present is usually accompa

nied by diarrhea. Anorexia is frequently seen the pain is usually in the lower right quadrant it is not surprising that 50 per cent of the cases have been diagnosed as acute appendicitis and operated on for that Hemorrhage from the bowel occasionally

Anemia is a common sign of regional enteritis and some temperature elevation particularly with acute exactivations is common. The temperature may be normal during remissions or may show a slight rise in the atternoon. The white blood count may be elevated to 20 000 in the acute phase or may fluctu ate between normal and that commonly associated with acute appendicus. The blood sedimentation rate is usually elevated. Not infrequently on abdominal examination a boggy mass may be palpated in the right lower quadrant. A mass with tender ness is sometimes palpated on rectal examination

X ray examination is frequently referred to as the most important diagnostic sign. Intestinal fistules or the narrowing of the luminal shadow in the terminal leum (Kantor's string sign) may be dem onstrated When present, this sign is practically

pathognomonic of regional enteritis. The author considers the points mentioned im portant in differentiating regional enteritis from acute appendicits, intestinal tuberculosis amebiasis

diverticultis, and chronic ulcerative collins In the author's series of cases the following com plications occurred in order of their frequency (1) an involvement of segments of the large bowel apparent ly as direct extension from involved small bowel seg ment (6 cases) (2) positive Kantor's sign (3) fistul ous communication within the abdomen-internal fistules (6 cases) (4) fistulous communication with the abdominal wall—external fistulae (4 cases) (5) obstruction (3 cases) (6) skipped areas in the small bowel (3 cases) (7) apparent subsidence of symptoms and absence of roentgenological signs without operative interference (3 cases) (8) hemorrhage (1 operative interference after operation (1 case) (10)

Of the 3 cases which cleared up without definitive fistulae or fissure in ano (1 case) surgery the first at operation showed six areas in the jejunum and jleum typical of regional enteritis with healthy bowel from 1 to 3 feet in length between the diseased argments. Because of the extent and dis tribution, the patient s abdomen was closed without resecting any bowel. Postoperatively penicillin was given with a rapid improvement in symptoms and a negative x ray of the bowel. The second case was diagnosed as regional enteritis after the Patient had been operated on for acute appendicitis by another surgeon. Six months later at cellotomy scarcely any evidence of the former scate process was found. The third case was a similar condition which im proved so much clinically that a second operation

Penicillin was used in 5 cases, all of which showed was not considered warranted prompt clinical improvement. While it may be speculative it is believed the drug was a definite factor in the amelioration of symptoms

The literature preponderantly favors surgery as the treatment of necessity Elliott Cutler of Har vard University still believes the disease should be treated medically unless certain complications arise. The author believes that surgical treatment is by all oilds preferable. All seem to agree that in the acute form of the disease no surgery should be instituted unless some complication such as obstruction makes emergency intervention imperative. It is inadvisable to remove a normal appendix in the presence of enteritis lest a fistula develop. If obstruction is present, most surgeons agree that a short-circuiting operation such as an ileotramsverse colostomy should be done. If the operation may be classed as elective the surgical proponents may be classed in two groups -those who advocate a a stage procedure and those

wh advocate a r stage procedure. The author resected the lesion and did an ilectransverse colostom, in r stage in all but r cases, in r of which a stage and in the other a 3 stage procedure was car ried out.

There was I death in the senes. A resection of the right colon was done with an end to-side illeotransverse coloatomy. The patient died a days later of urinary suppression, the cause of which was undetermined, but attributed to sulfa drug sensitivity At autopsy there was no blockage of the urinaferous tubules or peritonitis. Seniar R Broatom M.D.

#### Centeno, A. M: Diverticula of the Duodenum (Diverticulos del duodeno) Presus still argent. 945 32 1829.

The clinical and roentgen pictures of uleer of the duodenum are very well known but those of other diseases of the duodenum are not so well known. As a contribution to this subject the author discusses 55 cases of diverticulum of the duodenum seen at the National Dispensary for Diseases of the Intestinal Tract in Buenos Aires. Roentgenograms of a number of the cases are given

The first case of diverticulum of the duodenum was described by Chomel in 1710. The first stage in the hist y of the disease was devoted to autopsy descriptions, the second to reenigen examination and the third to clinical study. Case described the first roenigen examination of the condition in 19 and Fornell and Kay performed the first surgical operation for its treatment in 1913. Including the 52 cases discussed in this article the total number of

cases seen in Argentina has been 158

These diverticula are most frequent in the second portion of the dwodenum, then in the third portion and then in the fourth portion they are rare in the first portion. Those in the second portion are apt to press on Wirsing's duct and the common bile duct, and cause icterus and the symptoms of paracratitis. Those of other portions of the dwodenum often do not cause any symptoms at all and may be found only on autopay. Among the author's 55 cases 36 were in the second portion. In only 1 of the cases was the dwodenal diverticulum associated with diverticulus is of the colon. These diverticulus for the case was the dwodenal diverticulum associated with diverticulum associated with diverticulum.

generally solstary In only 2 of these cases was then a double diverticulum

These diverticuls may be congreital or acquired in the congruital cases all the layers of the Intesting wall are involved but in the acquired case the mucous and authorized here in the more than the middle period of tile and are about vote as frequent in males as in females. They are frequently complicated by other pathological conditions, and it has been claumed that any uncomplicated diverticals of the duodenum is symptomics. Of the authorized the duodenum is symptomics. Of the authorized the duodenum is symptomics. Of the authorized the duodenum is yet the creative resociated in other duesaes 7 with cystins, 9 with where of the duodenum is with camere. I the stomach, 2 is ulter of the stomach 1 with diverticulous of the colon, and 2 with displayment hermia.

The symptoms such as pain and vomities, are not pathognomonic and roentgen crammaton and quired for definite diagnosis. Icterus may be cased by infection but is not frequent as this part of the intention does not become infected earth.

intestine does not become infected easily. Uncomplicated cases should be given metal treatment designed to evacuate the diverticulant and prevent dilatation and infection. This may be accomplished by frequent change of positiva, the admanistration of antisparsoides and irrigates of the stomach. Small doses of sodium reliate or magnesium chloride attinuate the doctoral securitiva and aid in evacuation. Ten gram doses of bismuth carbonate, kaolin, or magnesium trifficiate may be given for inflammation. If surgery is we easily it consists of invagination or receition. If there is kiterius without calculus medical durings of the bille dots is preferable.

AUDRET G. MORGAT, M.D.

Hindmarah, T. A., Stewart, A. W. and Morrico, B.: Resection Operation for Gangreson Istussusception in Infants. Bril M. J. 1945, E. 48.

When in an Infant an acute intrastructories to comes irreducible and gangernous, not only is the choice of a sultable operation difficult but the result of the control of the control of the commonly does in these cases is either resection of the gangeron mass with end to-end or lateral anastomotics or teriorization of the mass with the formation of an enterostomy with a later attempt to close this file child survives. Suture of the proximal part of the intensaceptem has also been suggested the gangerous mass shorpling and periong per rectum. These operations are far from an action of the control of

In view of these results the authors have recently chosen to treat the irreducible gasteroom intrasterior by a mod feation of the Mikulier type of resection and are able to report 3 success. The danger of generalizing from 5 cases in recognish to the results in these 5 cases were so much better than those experienced with other methods that this report seems justified. At this point, however

it should be made clear that no major operation of this sort in an infant will be successful unless the child is given special preoperative and postoperative treatment by those who are experienced in modern pediatric methods and can Judge from hour to hour what measures are required to be taken A note by Brenda Morrison on these measures is included in

The Mikulica type of resection recommended is made possible in infants because at that age the this article croum ascending colon and transverse colon are very mobile. In both cases it was found easy after a small incusion of the peritoneum on the outer side of the intussusception to mobilize the mass and to bring it out of the abdomen with very slight traums. The next steps of the operation could then be performed expeditiously and with relative case

The operative procedure followed in both cases was aimilar. The preliminary attempt at ordinary methods of reduction having failed the intussusception was found to be gangrenous and some form of resection was therefore necessary The viable por tions of the Heum and colon were quickly joined together in the usual double barrelled Mikulica colostomy method, by two layers of continuous cat The satures, and the abdominal incision was closed around the bowel by interrupted sutures The con dition of both cases at the end of operation was satisfactory After 6 days the spurs were crushed and removed by the ordinary Mikulica method with the small crushing clamps. Six days later on the twelfth day after operation the stomata were closed after the bowel ends had been freed and turned in

The first patient has now made an excellent and permanent recovery The patient has gained satis actorily in weight, and a slight tendency to diar thes, due to loss of the ileoceral junction has cleared up. The second patient made an excellent recovery after operation, and it is anticipated that this patient also will return to normal health. JOHN E. KIRKPATRICK, M.D.

Newton F C. and Blodgett J B Succinylsulfa thereole and Intestinal Suction in Surgery of the Large Bowel Surgery 1945 18 200

There have been two recent important improvements in the operative preparation of patients for surgery of the large bowel. The first is the use of the Miles Abbott tube and the second is the use of chemotherapy to minumize the number and virulence of organisms within the lumen of the bowel article is a statistical report of the authors experi cocc at the Peter Bent Brigham Hospital Boston with these two adjuncts to colon surgery It compares the results in a series of consecutive cases of resection of the large bowel prepared by these two techniques with a series in which they were not used

Until recently proximal colostomy has been widely used in preparing patients for resection of the large bowel. The advantage of preliminary coloriony is that, preoperatively the bowel is relieved of distention and may regain its function and the

di tal lumen may be nearly emptied of its contents and postoperatively the site of anastomosis is kept at rest and the risk of blowout at the suture line from increased intraluminal pressure due to tem porary obstruction at the anstomosis is minimized A series of 114 cases of resection of the large bowel

was studied. The general preoperative and post operative care was the same in all except that in the test group (36 cases) succinylsulfathiazole was used before the operation and preoperative and post operative intestinal suction were carried out. In the control group (78 cases) primary colosiomy without continuity was the routine in resections with restoration of the continuity

The Mikulics type of resection was not required

The following data are of statistical significance in any cases of the test group

in the comparison of the two groups. The gross incidence of complications was re

2 The gross mortality was reduced from 19 to 3 duced from 58 to 25 per cent.

3 When similar operative procedures (resections and anastomoses) are compared it is found that the per cent incidence of postoperative infection is reduced from 43 to 6 per cent and the mortality is reduced from

The use of intestinal suction and succinylsulfa 22 to 3 per cent. thusole in the preoperative and postoperative care of patients who undergo resection of the large bowel or patients who undergo rescuent of the large power has a definite effect in reducing the incidence of postoperative infection and mortality JOSEPH GASTER, M D

# LIVER, GALL BLADDER, PANCREAS, AND SPLERN

Miristi P L.: Fourteen Years of Experience with operatoria catorce años de experiencia) Pressu suid

The first cholangiography practiced during opera tion was performed June 18 1931 on a patient with calculous hydropa of the gall bladder. The author reviews his experience with the method in the 14 years since that time illustrating his findings with case histories and cholangiograms

The method has demonstrated that there is peris tales of the common duct and that the hepatic duct contracts totally or partially both important factors in the filling and emptying of the gall bladder

in addition to contributing to our knowledge of the physiology of the bile tract, cholanguography is extremely useful in the diagnosis of many pathological conditions of this tract and has contributed greatly to better the surgical technique in opera tions on it. It gives the surgeon a so much clearer picture of the tract that he can avoid complications that were formerly frequent such as anatomofunc tional disturbances, residual lithiasis, cicatricial stricture of the hepatocommon duct and anom alies.

The important thing now is to help to generalise the use of the method rather than to discuss its value which has been proved beyond doubt.

AUDRET G MORGAN M D

Cole, W. H., Ireneus, C., Jr. and Reynolds, J. T.: The Use of Vitallium Tubes in Strictures and Absence of the Common Bile Duct. A. Surg. 1943, 132, 490.

The most serious stricture of the common bile duct and the one most difficult to correct is total "absence of the common duct which unfortunately is more common than the short stricture with sufficient proximal and distal ends for approximation. In 10 of this sense of 33 cases of stricture or absence (including a carcinomas of the common he patic duct) no duct could be found except the stamp at the hills of the liver. In this group he use of the vitalium tube was adopted and a few principles were established which helped the authors to arrive at a method of treating this defect which yielded faurly good results.

The method of repair of stricture depends upon the type of defect encountered. Defects can be divided tool four concountered. Defects can be divided tool four concountered (7) local that stodgood common duct, (a) stricture or absence of the terminal end of the common duct, (a) stricture or absence of the terminal end of the common hepatic duct, and (a) absence of the common and common hepatic ducts. In general, the utilization of rubber tubes in repair has not given astifactory results largely because they are unailly parsed within a short time. If they are returned there is a slightly greater tendency for the precipitation of bile saits in the lumen than in the lumen of vitallium tubes.

All (15) of the nubber tubes which the authors have inserted have been passed. Of the vitallium tubes which they have inserted 3 have been passed. Although the discussion in this presentation a related to the use of vitallium tubes in strictures or absence of the common dust, it is emphasized that whenever possible anastomosis should be made with no more than temporary intrataminals support. The bridging of defects by the insertion of a T tube serves the purpose of function quite well.

In stricture or absence of the terminal end of the common duct the authors are of the opinion that transplantation of the duct into the duodenum should be the first operation tried

The third type of defect is more difficult to repair than the first two largely because anatomosis of the duct at the bilus of the liver cannot be achieved with ideal technique. The insertion of a vitallism tube with the funnel end projecting into the stump of the common hepatic duct at the bilus and the lower end protruding into the common duct, as first performed by Clute is the procedure of choice.

When no remnants of the external duct can be found the problem of repair becomes much more difficult. The only possible method of repair is to anastomose the stump of the common hepstic duct

at the hilus of the liver to a loop of intestme. Is ability to obtain a good anastomous and the lact of an appreciable amount of duct wall are largely responsible for the poor results in plastic procedure when no duct can be found Cholangin is the pathological lesson feared in any repair of the tipe. while an even greater danger is the development of multiple abscesses of the liver The author are a the onlinion that in addition to the tendency for stricture formation to occur refins of food mai intestinal secretion into the intrahepatic does in very important in the development of chokarita Therefore they attempted mechanically to preme reflux of food up through the line of anastomers has the liver by isolation of the area from the level stream.

Two methods of reconstruction were emploid to accomplish this (1) amastomosis of the bits stump to an arm of the lejunum after the Ron principle and (2) attachment of the biles to a less of jefunum in which an anastomore is performed between the two loops at a distance from the kins anastomosis. Better results were obtained by somtomosis according to the Roux principle with the single arm of jejunum. The stump of the bersty duct at the hilus is approached by staying the the ventral surface of the liver and working from the lateral side. After the stump is located the jelman is severed about 1 foot or more from the luminent of Treits. The dutal end is closed by inversion with single line of continuous catgut suture. The end of the proximal loop is then adaptomosed to the conloop at least s feet from the end which is to be attached to the duct at the hilus of the liver little mesentery of the distal loop of Jerunum is not lost enough to permit approximation to the bilm of the liver without tension an opening is made is the mesocolon and the arm of jejunum is doesn't through this opening. The opening of the counter hepatic duct at the hills is dilated to a size with will allow introduction of the funnel and of the vitallium tube. The right and left hepatic date can be located by probing and occasionally the bad wil be found to divide so close to the hilus that the ordinary tube will be blocked by the septum between the ducts. Under such circumstances a take with a Y-end should be used so that each duct is cannulated. A purse string suture of silk is place around the end of the duct and the tube inserted Tying the sature should anchor the tube serured A purse string suture is then applied around the center of the line of closure at the end of the arm of jejunum. A small opening is made about a inches from the end of the jefunum and with a carre Pean forceps inserted into the fejurum and of through the closed end, the end of the vitallium take is grasped and pulled into the end of the intestive The purse string suture is then tied. Interrupted sutures anchor the end of the intestme against the hillus of the liver Two or three valves or beffer are made in the arm of the jejunum to prevent upand reflux of the intentinal contents.

Anastomosis of a loop of Jejunum to the stump of the hepatic duct at the hilus requires less operating time than the anastomosis of the Roux type but 3 of 4 patients surviving this type of operation de veloped chills and fever after a variable time. This rpe of anastomosis is not recommended unless an fective valve or baffle is placed in both arms of the oop particularly on the proximal side. An enteromaxiomosis must be made between the two loops of intestine at least 12 inches away from the anasto-

means between the duct and the jejunal loop, The authors have inserted 14 vitallium tubes in the treatment of stenosis or absence of the common duct. In 5 cases the Roux Y principle was used The results in 4 of these 5 patients were from good
excellent. The results following the use of a loop

Jejnnum for the anastomosis were not so satus ctory and chills and fever were common In 3 atients the proximal loop of the lejunum was inter apted at a later operation following which there ras abrupt cessation of the chills and fever in 2 atients. The operative mortality for 14 cases was

It is concluded that the best operation in the type of patients in whom no common duct can be found 143 per cent. n anatomosis of the stump of the hepatic duct to a single arm of the Jejunum which is at least 24 inches long and the walls of which have been folded to produce valves or baffles. Prevention of obstruction by the use of a tube did not prevent the occurrence of chills and fever unless reflux of the food was pre vented by the operative procedure. The vitallium tube has a definite place in reconstruction of stric tures and absence of the common duct, but it is indicated primarily in patients in whom no common duct whatsoever can be found and in patients in whom the common hepatic duct cannot be found JOHN L. LINDQUIST M.D.

# trunschwig. A. and Bigelow R. R. Advanced Carcinoma of the Extrahepatic Blie Ducta; Advanced Choleanglocholecystocholedochectomy

Seven patients presenting advanced carcinoma involving most of the extrahepatic bile passages and extending into the gall bladder and without apperent diffuse peritoneal spread or hepatic meta times, were subjected to radical resection of these ducts and of the gall bladder In one instance a portion of the head of the pancreas was also resected The purpose was to ascertain if palliation might not be afforded in this rather hopeless condition if most, or all, of the macroscopic neoplasm was removed.

The procedure a choleangiocholecystocholecone chectomy was carried out under continuous spinal snesthesia supplemented by ethylene and ether if

# Wechsler H. F. and Weimer J Linearies, Lithlands A. Report of 2 Cont. France, Adults. Gentromerology 1945 Feb.

The authors believe it is comme pancreatic calculate the condition are age of 40 and that the condition are agreed to sidered as a possibility among by sidered as a promp However fire younger are group However fire wale 28 years die younger white male 28 years die white male 27 years of age Both prowhite mair widences of proboth had a long history of digestar abdominal pain the symptomic of 8 and 10 years respectively of 8 and 10 years and progressive disease is any that the demonstration of cake

that the symptoms had been present for a consider able period of time. The etiology is unknown and the authors state that alcoholism cannot be the sole cause of the disease.

Both of the patients had suffered since childhood with intermitiant attacks of upper abdominal patin associated with bloating nauses, and vomiting. The pain was not relieved by esting and it was aggravated by fried or greasy foods, and by a large meal. Between attacks both patients complained of a dull soreness in the epigastrium, especially on arising in the morning. Neither of the patients had lost weight. There was no glycosuria nor saundice, and no evidence of hyratic dysfunction.

The rocaigenological findings in both cases were classical and of the most common type of pancreatic lithiusis. It is emphasized that patients with this condition may have a history of abdominal symptoms dating back to childhood.

EMIL C. ROBITEMER, M.D.

Mascheroni H A., Reussi C. and Clerici, L. E.: Failure of Surgical Treatment in a Case of Thrombophishitis of the Spienic Vein (Trombofelvitis de la veta spienica fractas del tratamiento quimprico en una observacio) Ren As well ar rest 043 50 10 5

Thrombophiebitis of the spieme vein alone is quite rare it may be prunary due to blood diseases or primary phiebosclerosis it may be secondary following compression by cysts or tumors, or from propagation of neighboring infections, such as puer peral infection, appendictis, or ulcer of the storach or it may be brought about by retardation of the circulation in general diseases such as cancer ma larts, or tuberculosis, or in a local circhosis of the liver

It is important to differentiate between philoitis of the splenic vein and that of the portal vein be cause surgery is indicated in the former and con traindicated in the latter. In philoitis of the trusk of the portal vein there is at first an asotes which later disappears hemorrhages from the hemorrhoidis and possibly the splenic arteries and a collateral circulation around the unbillious. When these signs do not exist the philoitis is probably splenic. There is apt to be repeated womiting of blood in both forms. Diagrammatic sketches of the two forms are given. On opening the abdomen the surgeon should confirm the probable clinical diagnosis by examination of the portal and splenic veins.

Eppinger operated on 14 cases of phlebits of the plenie vein with the following results 4 patients lived more than 10 years, 3 lived more than 5 years, 3 ded soon after the operation, 2 ded in the course 12 years and 3 were well a year and a half after the

operation but were not examined further.

The authors describe a case in a girl f 13 years who for several years had had repeated attacks of vomiting of clots of dark red blood. She was an in tractable patient, and examination and treatment were difficult. On admission she had fever and a

spience anomic with very great enlargement of its spience, which decreased in size after each sense mage and after the injection of adreasin. Spience thanks and after the injection of adreasin. In one finatance the features was repland as the result of a sharp glanding blow on the related abdonem in another case rupture of the full stosed by force of a powerful crushing nature was full in the third case the sphen was replared as the result of a sudden kick on the elastic overlying his.

WALTER H. NADLER, M.D.

Ewing, W. M., and Betts, R. H. Thoraconbdomical Injuries. Ann. Surg. 945 793.

Thoracabdominal injuries have shown a mir mply high mortal ty rate. Jolly reported a metality of 61 5 per cent in of cases and slicks, is reviewing 83 cases from the To isian and Izian campaigns, Jound's mortality rate of 48 per cent. Inasmuch as recent reports of abdomnal rawounds have shown a considerable decrease in mortality from the results of World War I and thorse things in the present war have not been fatal as often as form by the author believes that thorse-order as form the father of the state of t

abdominal injuries should likewise show a reduction m mortality rate.

A true thoracoabdominal injury signifies that the missile has traversed both the pleural and pentoneal spaces and has penetrated the diaphragm author believes that if separate missiles have entered ach of the cavities and the diaphragm is intact, aca or the cavines and the combined thorace, the condition should be termed a combined thorace.

in a 10 month period during the Italian campaign in 1943 and 1944 31 thoracoebdominal injuries were and abdominal injury treated by a thoracic surgical team in a field hospital. The patients had been seriously wounded and could not safely be evacuated. Of the 31 patients, 19 were operated on with 6 deaths a mortality of 10.7 per cent. Two were not operated upon these, one was transferred to another installation The second patient had a left thoracoabdominal in jury a right traumatic thoracotomy traumatic amputation of the right arm and a serious right thigh wound. In spite of 3 500 c.c of blood and 500 cc. of plasma, the blood pressure never was attained and the patient died 5 hours after injury without coming to surgery

In 10 cases the lesson was on the right side and in 18 cases, on the left side. One case was blaters, the same mustile having traversed the abdomen and both pleural cavities In the 10 right saided cases the liver was injured in every instance and was practically the only organ involved The right kidney and adrenal were each injured once Of the 18 left sided cases the spleen was injured in 10, the stomach in 8 the coloning the liver in 7 the jejunum in 4 the pancreas in s and the adrenal in 1 case. In the patient with bilateral injury the liver was the only abdominal

In 22 patients the injuries were produced by fragments of high explosive shells or bombs and in 7 organ involved

The authors state that sufficient evidence of thoracoabdominal injury to indicate operative inter ference is in most instances unmistal able Thoracic involvement is usually apparent a through and through wound of the costal cage or roentgenegraphic evidence of an intrathoracic foreign body Abdominal injury by a missile whose site of entrance h thoracle may be more difficult to determine. Perforating chest wounds may leave doubt as to the presence or absence of peritoncal perforation Penetrating must be located by posteroantenor

In questionable cases, physical signs are of little Abdominal pain and rigidity are so often and lateral x rays present in thoracic cases that they cannot be relied upon. Peristaisis suggests that injury to a hollow viscus has not occurred but occasionally it is present in patients with abdominal injury confined to the are or spleen, or the large bowel Pneumothorax and pneumoperitoneum as diagnostic aids are not

It is just as necessary to explore any doubtful practical for the acute phase. thoracoabdominal injury as it is every questionable

abdominal penetration Even if no hollow viscus is pencirated a damaged spleen may be fatal or an overlooked perforation of the liver may cause a bile empyema Any missile larger than 3 mm. in the liver may produce enough damage to warrant exploration The choice of surgical approach depends on three

factors (1) whether more extensive damage is ex pected in the chest or in the abdomen (2) whether the damage can be repaired easier from above or below and (3) the personal choice of the physician which is dependent upon his training and experience.

The advantages of the transthoracic approach are (1) if there is much thorace damage as well as abdominal damage the thoracic part cannot be done from below (2) certain upper abdominal leatons are more easily handled through the diaphragm (5) diaphragmatic repair is best accomplished transthoracleally (4) it permits externorization of the colon through a subcostal gridinon incision at a greater distance from the operative incision than if a celiotomy is done (5) postoperative pain is less severe from a thoracotomy than from a cellotomy (6) the patient can be carried in light anesthesis as abdominal relaxation is not necessary (7) although not apparent at first, considerable damage to the

intrathoracic organs may be present. Two factors favor the abdominal approach (1) it is indicated to repair lesions of the lower ileum, cecum ascending lower descending sigmoid and hepatic flexure of the colon and (2) if the thoracic hepatic flexure of the colon and (2) if the thoracic disturbance is minimal and operative interference is not indicated abdominal exploration prevents enter

Certain lessons are best done from above and ing another serous cavity questionable cases should be done from above, and others from below that one should not hesitate to do both a cellotomy and thoracotomy He opposes division of the costal cege to extend a thoracotomy incision on to the abdomen as it makes an unstable chest and increases the chance of postoperative pneumonia.

It is important to secure an air tight closure and stable thoracle cage complete and rapid re-expansion of the injured lung and maintenance of a clear tra cheobronchial passage during the postoperative pe H a surreon cannot accomplish these objec tives he should use the abdominal approach

A skilled anesthetist is a must for thoracocellot omics and the use of an endotracheal gas-oxygenether closed system is the author's choice.

For a thoracotomy incision the author uses the eighth to the tenth rib depending on the exposure

Careful closure of the diaphragm is essential and the author suggests a two-layer imbrication with destred

interrupted cotton or silk sutures. Temporary paralysis of the phrenic nerve by crushing enhances healing and the author has observed no unloward pulmonary complications at

tributable to the diaphragmatic paralysis. Liver lesions should be packed and drained sub custally in such a manner as to provide dependent drainage. Failure to do this may lead to bile peritonitis. Closure of the chest and lung re-expansion are of

basic importance in a transthoracic procedure and the author discusses his method of chest closure. In some cases the chest is drained under water usually by a catheters one anteriorly and one posteriorly in the second interspace. If not drained the patient must be frequently examined and any accumulation of air or fluid must be aspirated. In the present series the average number of aspirations in drained cases was 23 while in the undrained cases it was o 8 The author does not drain except in unusual cases, and he has found that complete early lung

expansion is more often achieved without drainage. There are a important points in regard to the postoperative care of the thoracic phase of thoracoabdominal injuries. The first is removal of air and fluid in the chest until complete lung expansion is achieved. The second problem is that of the removal of bronchial secretions, in many by bronchoscopy at the completion of operation. This was done in as of the 20 cases. In the ward signs of excessive bronchial secretion should be combated by supporting the patient's chest to make coughing more effectual this is not effective traches aspiration by catheter is tried and as a last resort, bronchoscopy. So im portant is this postoperative treatment that the author feels all members of the thoracic surgical team should be competent bronchoscopists. third factor is the control of postoperative pain which should not be severe in a thoracocciliotomy when the intercostal nerves have been paralyzed. Pain is better controlled by paravertebral intercostal nerve block than by resorting to morphine Of the 6 fatal cases I patient died of uremia on the

third postoperative day. At necropsy this patient had a large infarct of the kidney. One patient died during bronchoscopy after operation probably of vagovagal reflex" i died on the second postopera tive day of a fulminating purumonia another died of

strangulation on the ward the fifth patient died of

uremia on the third postoperative day. The less fatality in a patient with a right pneumothorur, a left thoracoabdominal injury a spleen injury and transection of the jejunum and colon, occurred on the operating table. The patient was in given shock with gross contamination of the pleural and peritoneal cavities, and failed to survive the occu tion even with adequate blood replacement.

The average time-lag from injury to operation was 8 hours for the fatal group and 11.4 hours for the nonfatal group which would indicate that probably the more severely wounded died before reaching my

medical installation.

Three of 8 patients with colon injuries ded (37 5%) but in only 1 patient was this the primary cause of death. Five of the 18 patients with left sided lessons (27 1%) died as compared with the figure of 9.1 per cent for the death of the o was right-sided lexions. These figures mirror the iscreased seriousness of left-sided lesions.

The death rate increases with the number of abdominal organs injured. One death in 15 (6.6%) or curred in this series when one viscus was injured, while 5 deaths in 14 (35 7%) occurred when 2 or more abdominal organs were injured.

From these cases the author draws the following conclusions

1 \n expert physician anesthetist experienced in administering intratraches! anesthesis is invalente

for the proper function of a surgical team treating thoracoabdominal injuries. 2 Fatalities rarely occur on the operating table. They are usually the result of postoperative pul-

monary complications necessitating tracked or bronchial aspiration by catheter or bronchoscopy 3 Pulmonary re-expansion after a thoracir oper-

tion is of utmost importance and must be pursed vigorously until the end is attained 4 Prolongation of the time interval from injury

to operation is not as significant in respect to mortality as are the factors of proper anesthesis and ROBERT R. BIGGIOW M.D. postoperative care.

Clayton S. G. Carcinoma of the Female Urethra on 8. G. Carcinoma of the remaie orethra Review of the Literature and Report of 3 (Review of the Lateracine size supplied of Cases) J. Obd. Gyr. Bril Empire 1945 52 508

Urethral cardnoma appears to be more common in the female than in the male Nichol stated that in the remain than in the made and account that is 149 cases had been reported in males and 262 cases in females. Hamann and Goebel found that it ac counted for o 16 per cent of gynecological carci nomas, but Menville found only 1 instance among

Urethral carcinoma is usually a disease of the 43,000 gynecological cases. postmenopausal woman the average age in 100

The disease is mostly seen in parous women, and cases being 53 years. following Ehrendorfer most authors have mentioned trauma or chronic inflammatory processes as etiological factors. Urethral caruncle is sometimes sus pected to be a predisposing lesion but in view of the frequency of occurrence of caruncle, it is hard to be sure that the supposed relation is not merely that Whitehouse divided the cases into urethral and of chance.

vulvourethral types, and the latter are found about twice as often as the former Whitehouse a account of the gross pathology is still one of the most valu able and it is difficult to add much to his description. Urcikral carcinoma. This is seen in two common

forms (1) in the usual form the growth appears as a malignant ulcer in the urethral floor most often in the distal urethrs, and (a) the less common form is that of perturethral induration extending for some length along the urethra with late ulceration I strongeleral carcinoma This occurs in 3 forms

(1) a vascular papillomatous nodule at the posterior

margin f the unthral orifice (2) a nodule that I reaks down t an ulcer in the vestil ule and (3) a scirrbous induration around the urethral orifice.

On microscoj ical examination the neoplasms are found to be of various types squamous cell care; nome columnar cell extendents both simple and adenocarcinoma), mucoid carcinoma and undiffer entasted types. In most of the series the squamous cell carcinoma predominates.

Menville has stressed the similarity of the growths

to neonlasms of the bladder

Urethral carcinoma does not produce much descomfort in the early stages and even after series symptoms appear there is often so much delay before advice is sought that extension to the bladder, vigina or lymph nodes may have already occurred

when the patient is seen. Perhaps the most common of the early symptoms is painful micturition. Difficult micturition or retention may occur in other cases, frequency Bleeding is a common symptom more especially with micturition. Local tenderness and dyspareunia also occur with the more superficial growths. Some

f the patients may report a swelling in the region

f the urethra.

On examination the growth may be seen project ing from the urethral ordice or in other cases it may be felt per requises as a line of induration along the urethra. Enlarged inquinal glands are found in about so per cent of the cases at the first examin ation. Biopsy is the final and recutial step in

As regards the primary tumor, the choice lets as surgical excision and irradiation is obviously afferded by the position and extent of the growth. If the posterior urethra is lavolved the growth can be enset only at the cost of permanent incontence, irradiation has less operative risk, although there is a possibility of both fistula formation and incoming the radioensativity of the growth varies with in

type and although it is generally stated that the squamous cell types are sensitive there is less agrement about the columnar cell types. As regards the inguinal glands, there is the same

choice between surgical exercison and fundation, and also there is fairly general agreement that sorgery offers the best results. The nodes are often inleted, and the overlying skin may not tolerate the largdoses of radiation necessary to reach the glands in their fatty bed

The results in general are disappointing Spath and Parsons for example, found only 1,9 survivos among 110 patients after 3 years. Tassing reports 14 cases, and in 5 of these the dusease was too idvanced for treatment. Of the 18 patients treated, 8 were subjected to Irraduction, with only 1 surveil, and 3 were treated by excision of the primary groats with Basset gland dissection all 3 surveils on the with Basset gland dissection all 3 surveils.

Three cases are reported,
DANIEL G MORTON, M.D.

## OBSTETRICS

### PREGNANCY AND ITS COMPLICATIONS

Greene, G. G.; Abdominal Pregnancy; 3 Cases Near or Past Term and 1 Case of Early Abdominal Pregnancy South M J., 1945 38 74

In abdominal pregnancy the problem of delivering the fetus is usually simple but that of delivering the placenta requires a difficult decision. There are three methods of approach namely (1) marsupialization of the placents (2) removal of the placents and (1) leaving the placenta in place. The first has been discarded by most experienced obstetricians of today because of the greater risk of infection in a wound which may be open for many weeks Removal of the placenta places both the patient and the operator in a dangerous position. On first inspection of the placental attachments one may think that the placents can be removed with ease, and find, too late that there is an unsuspected attachment which in volves a vital area. Such meddlesome surgery may cost the life of a patient who could have been spared

The 3 cases of advanced abdominal pregnancy presented bring out what seems the most desirable method of caring for the placents. In these the cord was cut short and tied. As much of the membrane as could be removed was cut away. The placenta was left intact and the abdomen closed tightly with out drains. Complications may arise and it may even be necessary to do a second operation for removal of the placenta, but this can be done with greater security later as the placents will be in a degenerative stage and possibly detached and lying free in the abdominal cavity Occasionally suppura tion may occur but this can be taken care of by simple drainage.

Since hemorrhage is a primary consideration what ever the approach the patient should be thoroughly fortified against it prior to operation. Anspach and others have agreed that the optimum time for operation is from 6 to 8 weeks after the fetus is known to have expired. This, of course is desirable if the placenta is to be removed but does not seem neces sary in most instances. The placenta will be absorbed by the body if the hands off policy is followed

Abdominal pregnancy can be diagnosed with less difficulty if one suspects it in any case which does not seem just right.

\-rays are very valuable when used in advanced abdominal pregnancy especially when a diagonal or other peculiar position of the fetus is noted

Alertness of the obstetrician and early diagnosis may save more infants. DANIEL G MORTON M D

Greene G G A 7 Year Review of Eclampsia with Special Reference to Treatment with Veratrum Viride. Am J Obd., 1945 50 427

Of the 150 patients in this review 104 were primi gravidas. This group of cases revealed that true eclampsia is far more frequent in the women in whom chronic kidney damage has been present for some time. Verstrum viride is not of much value. In more than half of the patients the eclampela began in the antepartum period.

During these 7 years every method of treatment known seemed to have been given a chance at one time or another

In the year 1937 many cesarean sections were done. It was in this year that the mortality reached its highest peak. Nine sections were done in 20 cases (45 per cent) that year Seven of the 9 patients ex pired. Five of the 7 were treated in the hospital for only 24 hours or less before operation was performed All of these expired. This emphasizes the urgent need for control of the eclampsia before any opera tive measure is attempted

Fifteen cases were seen from 1941 to 1942 in clusive. Fourteen of these received veratrum viride All of the patients recovered. The patients are treated without giving them any morphine or bar biturates Paraldehyde per rectum is the choice method of anesthesis. It was found that after treat ment had been started 50 per cent or more of the nationts did not continue to have convulsions or at most they had only a convulsions and in a short period of time they were rational and responding to questions

No attempt at delivery should be made until the convulsions have been controlled and the patient is rational for one or two days. A number of these cases will go into labor spontaneously during this period if not the induction of labor can be ac complished by the simpler methods, with drugs or some minor operation such as rupturing of the mem branes. A very small number of cases may not respond to any of these. If the patient is a primipara near term with a closed thick cervix cesarean sec tion can be considered and performed rather safely provided the eclamptic state has been controlled for a time but the patient is beginning to show evidence of returning to her former condition by a rise in blood pressure, an increase in albumin, and casts in the urine The author does not like to use bag in ductions in primipares for this or any other reason.

Eclampsia is a complication of pregnancy pre valent mostly among the young negro women in the South as the result of improper prenatal care.

EDWARD L. CORNELL, M.D.

Macaice, C. G. Il : Placenta Previa A Study of 174 Cases. J Obn Gyn Brit Empire 1945 52 313

Since 1937 all cases of antepartum bleeding ad mitted to the Belfast Royal Maternity Hospital have been treated under the direct supervision of the author. In this article he reports the results of the treatment of 174 cases of placenta previa which were classified as to location as follows Type I (low-lying)

218

TABLE I METHODS OF DELIVERY

	Ne of Caper	Staff- births or deaths	Per rest
Artificial rupture of membranes	52	7	3 4
ARM and Willett sforceps	0	0	47 4
Vermon		17	77 3
Cesarean section	68		3 0
Breech	6	5	83 3
None	7		14 3

50 Type II (marginal), 37 Type III (partial) 46

and Type IV (complete) 41 The physician who first sees a patient with pla centa previa is responsible for getting her to a hospital where suitable treatment can be administered The type of placental implantation can be determined and the program for treatment outlined only after careful vaginal examination. The time when the vaginal examination is made, however is of utmost importance to the final outcome for the baby Since many cases of placents previs manifest themselves early in the last trimester of pregnancy and since most of the infant deaths are due to prematurity delay in treatment to allow the baby to grow should increase the survival rate. The author contends that severe hemorrhage particularly in primigravidas, and further separation of the placenta usually follows vaginal examination, and cites several cases of "silent previas discovered at cesarean section for other conditions. The small hemorrhages which may occur from time to time in the unexamined patient are of little consequence

If the initial bleeding occurs near term no time should be lost in initiating treatment but several being caramheed. The average brits well as the large treatment but several being caramheed. The average brits well of the infants in the first 147 cases delivered at the time of the first bleeding was a pounds a ouncess with a fetal mortality of 47 per cent, and in the last 47 cases observed and examined later 6 pounds 13 ounces with a mortality of 6 per cent. The total fetal mortality and was 83 x per cent, as compared to x3.

ner cent for the previous 4 years.

The author states that the aite of the insertion of the umbilical cord into the placenta is of importance in fetal survival. If the cord is inserted low the baby is likely to die, whereas it usually will survive if the cord is attached high, on the portion of the placenta which remains adherent to the uterine wall.

The methods of delivery with the associated fetal mortality are outlined in Table 1. The lower segment cessrean section is preferred, but care should be taken that the placenta is located before the uterine inclision is made so that it is not incised

J ROBERT WILLSON M.D.

Vartan C. K.: The Behavior of the Fetus in Utero, with Special Reference to the Incidence of Breech Presentation at Term. J Ohn Gyn. Brit

Empire, 1945 52 4 7

Studies show that spontaneous cephalic version from a breech presentation normally occurs during

pregnancy It was formerly thought that breek presentation occurred most commonly when there was a decrease in size of the pelvic cavity bot observation of the cases shows that the faties which prevent spontaneous version are the real citological factors which persist to term.

Three theories formerly held to explain un cephalic rather than breech presentation occurs are

contradicted

1 The statement that the smaller circumferers of the breech at term causes it to present in a small pelvis rather than the head is refuted by the observation that presentation is decided long before the fetus attempts to enter the pelvic brim.

2 The theory that the smaller circumference of the fetus adapts itself to the small end of the stems is refuted by the observation that the uterus at tens is not pyruform especially in the multigravids or is

hydramnios.

3 The argument that gravity causes the best present rather than the lighter breech is related by the observation that breech presentation is such more common early in preguncy than later as that the woman's upright position is not constant maintained.

One thousand cases of breech presentation ocur ring during some period of pregnancy were observed in a series of 3.874 patients. Breech presentation b regarded as a common occurrence up to the thirty fourth week of pregnancy, with spontaneous critain version between the thirty-first and thirty tibi weeks in most cases. In this series spontaneous exp alic version occurred in 680 of 1,000 cases. The inflaence of parity on spontaneous version is unimportant; in this series the incidence was equal m primipant and multiparas. Reversion seldom follows spoatzaous version it occurred in this sense in only 15 women, most of them primiparas, of which underwent a second spontaneous version. Extern version has a higher reversion rate than spontaneous version of 330 cases in which external version and done as per cent (77 cases) had a reversion to breek presentation Other observers have arrived at figure of 33 3 and 21 per cent. External versions performed after the thirty third week show a lesser tendency to reversion than those done earlier among 22 per cent of falled versions in this senses, 36 cases presented by the breech at barth, 28 had spontaneous reversion and 13 were reverted by the obstetrican The majority of persistent breech presentations show an extended attitude at term a small propor tion show very little liquor (in this series 3%) most

of them occur in primipatars (3; in this series). Spoul ancous podule version occurs occursions[1] it was observed in 134 cases (3,4%, of the total \$8,75) and in 45 of these is occurred as a missi movement, one-fourth of the cases readjusting therefore, No organic or other factor was appetred influencing spontaneous podule version, but of 8 breech presentations at both 1a cost of the 51 unbernsided bytech deliveries the infant was strillored.

A STATE OF THE STA

日本日本日 日 日本日本日 日本日本日

日本日本日本日本日本日

Patients should be informed that the breech presentation is normal at a certain stage in the pregnancy furthermore it should be realized that spon taneous version occurs in 3 out of 5 patients. The cause of spontaneous version is not as easy to explain as the cause of its nonoccurrence. It apparently happens that spontaneous version does not occur (1) when the fetus is abnormal or premature, (2) when there is little liquor (3) when the limbs are extended and (4) when twin fetuses mutually

prevent each other from turning

In performing external version one must induce the fetus to undo its extension and then to turn it rather than to attempt to force around an inanimate object of the wrong shape. Gentle cephalic pressure will induce vigorous movements and often undo the extended attitude. Gentle pressure on the facial aspect and backward turning is often successful when forward version fails and may be repeated weekly or oftener Anesthesia is inadvisable and unlikely to help in most cases. Accidental hemorrhage at the time of version is very rare. The incidence of death because of dystocia in breech delivery is no higher than in the case of vertex delivery The mortality rises when a difficult delivery a added to a breech presentation, and no woman with a large baby in persistent breech presentation in the extended attitude should be allowed to de liver herself

Skigrams have been most valuable in breech cases for determining the fetal attitude and the amount of liquor and therefore have aided in the subsequent management of the case whether it be induction of premature labor or casesarean section at term. Printip B Crass, M.D.

O'Driscoll, D.T.: Acute Hydramusios. A Brief Survey of the Recent Literature, with the Report of a Case Simulating Concealed Accidental Hemographies. J. Obs. Gyn. Bril. Empire. 1945, 52 496.

Acute hydraunies has been reported go tunes in the literature. The cause is atill unknown. The annichte fluid is generally regarded as of dual origin. On the maternal side the fluid comes from the blood plasma and is probably changed by its passage across the placents and aminon. The aminon is capable of true accretory activity The fetus probably contributes by unnary secretion and by transudation from the letal surface and umbilical cord. Under normal conditions the fetus also probably helps to regulate the amount by its constant swallowing of higher with the subsequent passage of excess fluid into the fetal circulation and across the placenta into the maternal blood stream.

In hydramnios therefore, pathological conditions both on the maternal and on the fetal side may be tiological factors

Analysis of the last 40 cases of acute hydramnios that appeared in the literature revealed the following associated conditions 8 cases with twins 7 cases with anencephalus 2 cases with teratoma of the

neck I case each with multiple deformaties, atreas of the esophagus congenital adenoma of the lung and hydrocephalic anophthalmic monster. The conditions present in the mothers were ascariasis appearing acutely in puerperium diabetes mellitus and eclamosia.

In this article, the author reports 1 case of scute hydramnios simulating concealed accidental hemor rhage. The patient was delivered of a stillborn

anencephalic fetus

The case is of particular interest because the patient presented a typical picture of concealed ac cidental hemorrhage. Not until the membranes were artificially ruptured and the ammotic fluid was forcefully extruded was the diagnosis made. The symptoms were sudden severe abdominal pain with vomiting. On admission to the hospital the patient looked pale and shocked. The abdomen was extremely tense hard and tender occasional painless contractions were palpable. Rectal examination revealed the cervix to be closed. The uterus reached to two fingers below the xyphoid.

The main points in the differential diagnosts be treen acute hydramnos and concealed accidental hemorrhage are (1) the duration of the symptoms, with a slower onset in hydramnics (2) abdominal calargement, greater in hydramnics (3) hallotte ment will favor a diagnosis of hydramnics (4) in vestigation of the previous history (5) abdominal puncture of the uterus by a fine needle (Courtois) Other conditions requiring differentiation as

ovarian cysts ascites and multiple pregnancy. The treatment of acute hydramnios is usually conservative. If the fetus is normal, an effort is made to carry the pregnancy to term. This can be done occasionally by frequent decompression of the uterus by the technique of Courtois. If the pregnancy is at term or the fetus is deformed labor may be induced

Draining of the fluid, either through the abdomen with a needle or by rupture of the hind waters with a Drew Smythe catheter, is recommended by the author as a desirable method of inducing labor

The author concluded that acute hydramuos occurs in patients who would develop hydramuios in any case but because of the introduction of an additional factor the symptoms arise acutely. The additional factor is a uterine musculature that is oversemsitive to undue stretching caused by the presence of an extra amniotic sac or traums.

HARRY FIELDS, M.D.

Burch A. E.: The Association of Erythroblastosis Fetalis and Accidental Antepartum Hemor rhage J Obst. Gyn. Bril Empire 1945 52 463

It is concluded from the evidence in two senes of cases that Rh negative women are abnormally prone to have accidental antepartum hemorrhages. It is also postulated from the series that the ensuing placental damage may be the factor which produces erythroblastosis in the offspring by allowing the transplacental passage of antigen and agglutinogen. In so of a case of expirabilastosis feals in the Oneen

Charlotte Hospital series reported there was an associated premature placental separation and antepartum hemorrhage the association of two such rare conditions seemed significant although the number of cases was small

Among the 10 cases of accidental antepartum hemorrhage reported from St. Alfere a hospital s of the women were Rh negative and had Rh positive husbands and a had anti Rh agglutining. Three of these women had a hemorrhage just prior to de livery and 1 of them had a jaundiced baby 1 gave birth to a child with gross hydrops, and the third had a stillbirth. Two of the women had a hemor thage some weeks before delivery and both had stillbirths. In all but 1 of the cases there was an association between (1) the time between delivery and bleeding, (2) the severity of the crythroblastosis and (3) the titer of the agglutining This suggests possibly the advisability of an early induction of labor when agglutinus are present in the mother in order (1) to prevent hemorrhage in the mother or (2) to prevent crythroblastosis in the infant, but this must be balanced against the risk of prematurity

The importance of the Rh testing of mothers is stressed especially because Rh negative mothers are prone to have hemorrhages on account of their isolmmunization and run the risk of incompatible

transfusions.

In explaining the disproportionately low incidence of erythroblastosis in the offspring of even Rh negative women authorities are quoted as stating that (1) many marriages are childless of produce only 1 child (2) there is a variable potency of the Rh anticen in the infant which produces agglutining in the maternal blood (4) there is a variable ability of the placenta to prevent the passage of the antigen (4) there is variable maternal response to the introduction of the Rh antigen into the blood stream and (4) there is a variable ability of the placents to prevent the passage of the agglutinins.

Parter B Crear, M.D.

Soloway II M : Control of Syphilis in Presnant Women J Am M Att 1045, 120 500

The Illinois Department of Public Health has re ported the results of its plan for the prevention of

congenital syphilis.

The plan calls for a blood specimen from every pregnant woman to be sent to an approved labora tory for scrologic examination. The report is sent to a central agency which contacts the family physician Information in regard to treatment as well as the necessary drugs are provided if so desired. In a klition, every facility to assure adequate treatment. and follow-up is provided f r the physician.

Adequate information was available in 1.448 cases. In the remaining 213 it was considered inadequate

for a variety of reasons.

The most significant finding was the relationship of the outcome to the onset of treatment. When treatment was started before the end of the fourth month the t-tal fetal loss was 6 per cent. Treatment delayed until the fifth month yielded a fetal loss of 17 per cent. Beyond that time the fetal lon rescied 40 per cent and in the absence of treatment a increased to 73 per cent

Reactions to antisyphilitic treatment seemed b-There were no fatalities, although n significant

serious reactions were reported.

This report stresses the well known fact that ongenital syphilis can be prevented by early discour and adequate treatment. In prevention of consensal syphilis the emphasis should be placed on early or tection. This can be accomplished if the patient are educated to seek early prenatal care and if the physician does a routine serologic test. Once the disease is diagnosed every effort must be sade to carry out adequate treatment and follow-up stades on both the mother and child.

JAMES F DOWNELT MD

Hudson G S. and Rucker M P Spontaneous Abortlon J (m 11 Am 945 29 542.

Statistics on the frequency of spontaneous shot tion vary widely This study covers 1,000 counts tive obstetrical cases in which there were too shortions of all types. When the 12 therapeutic and 2 criminal abortions were subtracted there resumed 04 spontaneous abortions, an incidence of 94 per cent.

The incidence was then noted in relation to certain factors and compared to the anticipated incident

of apontaneous abortion.

In patients who had had previous children or abor tions, the incidence was higher An increase a noted also in obesity, pelvic inflammatory dress, retrodisplacement, fibroids, hypothyroidism, da betes, in women who used tobacco and in most who gave a history of previous sterility. The hy crease was particularly prominent in the last for mentioned instances.

Factors which the authors stated had no effect es the incidence were the marital status, syphilis scatt upper respiratory infections, and falls.

JAMES F DOWNELLY M.D.

# LABOR AND ITS COMPLICATIONS

Mandel, H. S., Graff S. and Graff A. M.: Places tal Senescence and the Onset of Labor 4s. Old 1945 50 47

Estimation of the nucleocytoplasmic ratio reveals that the placenta ages in a uniform and continues manner from approximately 86 per cent at 1 months to 3 6 per cent at term The growth of the placenta conforms to theoretical and statistical beof growth. The toxemias of pregnancy has e se effect upon the placental age as measured by the nucleocytoplasmic ratio Death f the fetes in atero lowers this ratio i.e., causes increased aging, proably by some aut lytic process.

There is no correlation between placental searcence and the onset of labor

EDWARD L. COR CL. H.J.

#### PUERPERIUM AND ITS COMPLICATIONS

Fulton A.A.: Vitamin Cand Lactational Mastitis. Bril. II J 1945 # 488

Of a Scottish clinics for pregnant women designated by the author as clinic A and clinic B respectively each served about half of the town, and there was no distinction among the patients received as to social status or other condition. The group of patients attending clinic A who received ascorbic scid is referred to as group B and consisted of 114 women. The patients attending clinic B did not receive ascorbic axid being the controls this group is referred to as group B and consisted of 126 women.

In group A each expectant mother was given so mem, tablets of ascorbic acid daily at about a months before the onset of labor and until about 6 months following childbirth. On admission to the Maternity Hospital all of the patients in both groups were given the saturation test for vitamin C as devised by Harris and Abbasy (Brit M. J. 1037) 2 1429) The patients in group 4 required an average of only 1 673 mgm and those in group B 3 076 mgm. for saturation yet approximately the same percentage (25%) developed mastitus although the former were more favorably situated as regards the two factors considered to be predisposing causes of mastitis in lactating women primiparity (in from 47 6 to 52.4%) and delivery in the hospital (15 women of group A were delivered at home)

From these results it would appear that vitamin C administration per se has no influence in reducing

the incidence of mastitis

The subsequent tests on the patients with mastitis after the saturated state had presumably subsided from the first saturation tests (in about 3 weeks) showed that (as in the first test) on the average of 1,470 mgm. of ascorbic acid were required to saturate the patients of group A and 3 117 mgm were required to saturate the patients of group B. The saturation test according to the standard of the League of Nations showed that 63 7 per cent of the cases of group A reached the saturation stage within

2 days of the beginning of the test period whereas all of those in group B reached this state but at a much later date

2 I

The patients in group B were even in a somewhat better condition with regard to the severity of the mastitis because the process subsided without suppuration in 9 of the women in group B but in only 3

of those in group A

The author admits however that there are a number of vitating factors at work in this study, the most important being perhaps the fact that no account was taken of the possible effects of other food deficiencies in these patients and also the fact that the vitamin C administered was swithetic whereas it is possible that the maximum benefit may be obtained only when it is given in the form of natural foods.

### NEWBORN

Gamble, T. O. Miller L. C., and Tainter M. L.: Benzyl Penicillin; Clinical Toxicity and Efficacy by Mouth in Impetigo in the Newborn Infant. Am J. Obst. 1945, 50, 514

The benzyl ester of penicillin given by mouth quickly cleared 16 attacks of impetigo contagiosa in 15 miants in a maternity hospital and terminated a

protracted epidemic.

This new form of penicilin as stable at room tem perature and can be supplied to the physican readfor use. It is as effective by mouth in impetigo as is the sodium penicilin administered by infection. The great advantage of being able to give bens; I pencillin orally marks a major advance over the previous injection, therapy in managing this difficult condition. The new therapy avoids staining the skin and linen as in the treatment with dyes and also does not require the painful surgical removal of crust as in the local therapy of impetuso.

The effectiveness of benzyl penicillin demonstrated in this study points out the need for extensive tests of this preparation in other types of infection.

### GENITOURINARY SURGERY

### ADDENAL KIDNEY AND HERTED

Huff, F. M., and Boder, W. P., Jr.; Renal Hypoplace with Hydroureter and Primary Amenor rhea. J West Balt., 1045 ta.

The frequent coincidence of genital and upper urinary tract anomalies has been noted, and reports of many cases have emphasized this combination of abnormalities

The case here presented is of interest by reason of left renal hypoplasia, a greatly dilated and tortuous ureter with a stricture of its intramural portion aberrant vessels crossing the lower preter and promary amenorrhea, assumed to be due to consenitally defective internal genitalia

While renal hypoplasia is not uncommon, the great preteral dilatation found with it in this instance is unusual. The futility of endocrine therany in this case strongly suggested an end organ structurally incapable of remonse. From this experience it would appear that the complaint of primary amenorrhea justifies investigation of the urinary tract. IONN E. KIRKPATERTE, M.D.

Newman H. R.: Renal Disease in AAF Regional Station Hospital, J. Urel. Bult., oas to 156.

The incidence of renal disease is considered to be at the lowest figure during the draft age of from 8 to 18 years.

The present study includes 1 2 cases of renal lexions in patients between the ares of 18 and 18 years. This study reveals the large number of cases of renal disease which may be encountered in an average sized station hospital (approximately 500 beds) over a period of 12 months. In this period of time there were approximately 475 urological admissions, and about 1,200 patients were seen as out patients. Patients with venereal disease were not included on this service

The renal lesions most often encountered were congenital anomalies, infections, and calculi on the other hand penhroptosis, albuminuria, hematuria of unknown origin, nephritis, and tuberculous were found to be relatively uncommon.

TORY E. KIRKPATRICK, M.D.

Neebit, R. M. Keitzer, W. A., and Lynn, J. M.; The Prognosis of Renal Tuberculosis Treated by Nephrectomy and the Outlook of the Pa tient Who is Considered Unsultable for Opera tive Treatment. J Urel. Balt. 1945, 54

Data are presented on 260 cases of genitourinary tuberculosis which have been followed for a period of s years or more. It is pointed out that in this series males were affected more frequently than females, in a ratio of about a to I and that the urine in about one-third of the cases was secondarily injected by organisms other than the tubercle bacillus. Fifty and three tenths per cent of the penhaertoment natients are living an average of 11 years after men tion, while 81 3 per cent of the patients not operated upon have died in an average of 3 years. The author were unable to demonstrate that an accommendar cenital complication in the male adds to the mor tality of renal tuberculosis and they assume that the higher death rate among males is due to the higher mortality of tuberculous generally in this pertuche emon n

Three facts derived from these figures have novel

to be statistically significant In nephrectomized patients, a lower rate of survival is found in the group in which acid iss bacilli have been demonstrated in the prine from the kidney not operated upon, by suines of fromk tion than in those with normal urine on the sound

2 In tuberculosis of the urinary tract the survival of females is greater than that of males

The mortality rate of genitourinary tubercalors is adversely infinenced by the presence of bone and TORDY A. LONDY M.D.

foint, or pulmonary lesions.

Dourmankin, R. L.: Cystoscopic Treatment of Stones in the Urster with Special Reference to Large Calcuil, Based on the Study of 1,59 Cases. J. Urel. Balt. 945, 54 245.

The author presents a series of 1,550 cases of ur-teral calculi, situated at all levels of the ureter and renal pelvis, and lists the results obtained by cysts-

scoole manipulation in 1 253 cases. The methods of nonoperative treatment of anteral stones are classified and evaluated by the author es follows

Industiling ureteral catheter This does not produce dilatation of the ureter adequate enough for the passage of large calcull. It is of distinct value, combact with the administration of sulfa drugs, in cases is which renal infection is a complication of prinary blockage, and should be utilized in these cases prior to attempts to dilate the ureter with rubber bap and metallic dilators.

Methods for forcible removal of sectoral calcul-These include the use of metallic books, calcul, and baskets and are condemned for general use, as they are dangerous in both theory and practice, resulting in serious damage to the ureter in many instances.

Dulatation of the wreter This is done at or below the level of the calculus to a degree adequate to allow passage of the stone. It was the method of choice in the management of ureteral calcul in this series of cases.

For the purpose of determining the results of intraureteral manipulation, the stones were divided into two large groups A, small calculi, measuring less than 5 mm in width, and B large calculi, mesturing 5 mm. or more in width.

There were 780 cases in group 1. Tabulation of the results shows that excluding 48 cases of spontaneous passage of stone 41 cases which were lost to observation and 2 cases in which no cystoscopic manipulation was attempted because of the severity of the renal infection and in which nephrectomy was done, there were only 2 of 689 cases treated in which the cystoscopic manipulation failed or that a successful passage of stone followed cystoscopic intervention in 99 7 per cent of these cases. Six cases of complete anula were observed in this group 4 cases showing billateral calculous obstruction and 2 showing smutas of apparently reflex organ.

There were 71 cases in group B There was spon taneous passage of the stone in 10 cases and 24 cases were lost to observation. Intraureteral manipulation was successful in 484 cases or 85 9 per cent. The principle of providing ample room for the downward passage of the stone at and below its level was followed in this work. This was achieved by dilatation of the lower end of the ureter with the author's metallic bougies, and by unlar rubber bags at the higher levels. There were no instances of ruptured ureter or mortality resulting from instrumentation Operative removal after cystoscopic manipulations had failed was necessary in 80 cases or 141 per cent

In 134 cases of group B operation was performed without a preliminary attempt at cyatoscopic ma nipulation for one of the following reasons the stone being obviously too large, acute infection, advanced chronic infection and hydronephrosis an emergency (hemorrhage, impending uremas, or ruptured kid ney) a large renal calculus requiring operation associated with a stone in the upper ureter on the same side renal destruction on the opposite side due to a renal calculus associated with a sintly large stone in the lower end of the ureter bad impaction, an analyment of the uniformed incident under stricture empyems of the ureter following nephrectomy the association of stone with renal tuberculosus or the patient's refusal of cystoscopic treatments.

WILLIAM W SCOTT M.D

### Lazarus, J. A., and Marks, M. S.; Primary Carcinoma of the Ureter with Special Reference to Hydronephrosis. J. Ursl., Balt., 1945. 54, 140.

In 1914, after a careful search of the laterature one of the authors was able to collect 68 cases of primary carcanoma of the ureter, including 3 of his own Since then 115 additional cases have been reported, which indicates an increased alertness on the part of urologists to the possibility of this disease rather than an actual increase in incidence.

Of the total number of tumors 4s per cent were of the nonpapillary type. Malignant neoplasms were situated in the lower segment of the ureter in approx imately 50 per cent of the reported cases, and were associated with ectasis of the renal pelvis in 464 per cent and of the ureter in 43 7 per cent because of the tendency of these tumors to occlude the lumen of the ureter. The greatest prevalence of this disease oc curred in the sixth and seventh decades Ureteral carcinomas show marked invasive and metastasizing tendencies particularly to the regional lymph nodes (28 9 per cent) liver (14 9 per cent) and bones (12.8 per cent)

Although pain hematuras and the presence of an enlarged kidney are supposed to constitute the char acteristic triad of symptoms of this disease, it was found that hematura alone was by far the out standing symptom, having occurred in 70 5 per cent of the collected cases. A clear cut and persistent filling defect in the urterogram especially when associated with ectasus of the segment of the urter duretly above such a defect in the suthors opinion, constitutes the only pathognomonic sign of ureteral tumor

The chances of demonstrating filling defects in unterograms would be enhanced if repeated attempts were made to obtain good ureterograms in all cases which (1) disclose an obstruction in the ureter, (2) bleed through the ureteral exthete as a result of manipulation at the site of the obstruction, and (3) fall to disclose a calculus at the site of the obstruction Failure to recognize the presence of this discase has led urologists to remove hydronephrotic kidneys only to learn later to their great chagrin that the hematura had recurred and necessitated a second operation for the removal of the tumor bear ing segment of ureter

The procedure of choice in the treatment of this disease is complete extraperitoneal nephrourierer tomy. It is recommended that a cuff of vesical wall surrounding the ureteral meatus also be removed in cases in which the tumor is situated low down in the ureter and especially when the ureteral meatus is involved.

A careful review of the literature has further strengthened the authors belief in the dangers of incomplete urological surveys for so-called minor urological complaints and a detailed history is given of a case in which the patient was perfunctorily treated on and off for 15 years for cystins without being subjected to a thorough urological survey. It is believed that the lesion which was found could never have progressed to such large proportions had ureteral catheters been passed during one of the episodes of so-called cystifis.

### GENITAL ORGANS

MacLeod D: The Glandular Nodule in Benkin Glandular Enlargement of the Prostate; Ita Development and Cause Bru J. Urel. 945 7

os no benign glandular enlargement of the glandular nodule in benign glandular enlargement of the prostate is as

I At any one time during the growth of the prostate there are present groups of tubules at times unrecognizable which arise from the terminations of the primary and subsidiary tubules of the prostate. They may be collective as in the prespermatic region, or individual.

2. With further increase of the glandular tissue in general, a circumscribed resistance to the growing groups is created in due course by the tissues in which they are situated. It is caused indured by by a passive force applied to the tissues from the periphery of the prostate as a whole and also from that of the prespermatic region.

a Growth of the groups against that resisting tissue is accompanied by and causes the formation of, circumscribed capsules of fibrus and/or compressed glandular tissue about them the groups are thus isolated and so form the glandular nodules associated with the benign enlargement of the prostate

4. Within the limiting capsules growth of the groups may continue actnous formation and intra actnous epithelist proliferation are followed by acin-

ous dilatation and rupture.

The direct cause of benign glandular enlargement of the prostate is continuity of the active glandular growth against a passive and circumscribed resist ance derived from the periphery of the prostate as a whole and also from that of the prespermance region.

The glandular module in the benign enlarged prostate is evidence f an attempt to limit the size

of the gland

Peripheral resistance to the glandular growth be comes duly effective in the upper parts of the pros-

tate first and it the lower parts last, because of the last portionate increase if growth in the talk goods and glan lular nodules are in point of time and place likewise formed.

The absence of benign enlargement from the uper part of the posterior lobe of the prostate is due to the destruction of its groups of tubules by pressure from the enlarging lobes in front of it absence from the lower part is caused by lack of adequate periphent resustance to its growing groups of thobles.

Bengen glandular enlargement of the termul parts of the lateral lobes of the prostate is equally as rare as the same condition in the posterior lobe and is due to lack of adequate peripheral resistance to the growth of the tubules in those parts.

### MISCRILANEOUS

Yamauchi, 8.: Chyluria; Clinical, Laboratory and Statistical Study of 45 Personal Cases 06served in Hawaii J. Ural. Balt., 1945-34-34.

The clinical, laboratory and pyelographic stedisbased on 45 personal cases of chyluria are carefully compared and correlated with those if the case recorded in the literature and a comprehensive jicture of chyluria is here presented.

The etiology and pathology have been discreted, chiefly on the basis of the author's experiences with his own material, hence they represent his own years. This material has been added as an adjust to the main material and the analysis of the records, to aid the reader in obtaining a comprehensive pic

ture of the disease. The individuals suffering from chyluria had all been exposed to filariae during their lifetime, but filariae were never demonstrated in their blood urine or as in some cases, tissues. The long pened from the last possible exposure to the filarae t the onset of chylurfa (in many of these cases) the absence of cosinophilia (in the majority) and several other factors indicate that filariass probably predisposes the patient to this condition but it does not actually initiate it. However anyone who has been exposed to this nematode becomes a potential canddate for chyluria anytime, even many years after the exposure Thus, the incidence of this disease can be expected to rise in regions where filariasis is not prevalent, such as the northern United States

armed forces return from regions where it is endema.

Cause of chyluria. Formix replure caused the carting cause of chyluria. Formix replure caused the carting stasis results in a lymphaticouring communication, and chyle appears in the voided write if the ruptured lymphatic vessels alresdy omnian chile. Except in a few instances minimal pathologic changes sufficient to from varied danier obtrieved in the lymphatics without criminal pathologic changes sufficient to from varied danier obtrieved in the large retroperitioneal imphatic vessels and thoracted duct. Preparancy endocrackit and prostatic hypertrophy so frequently found uit thus condition become logical concomitant occur.

rences instead of bizarre associations when viewed in this light

Chyluna is characterized by the appearance of chyle per se in the voided urine. The presence of fat granules in a colloidal state the presence of albumin crythrocytes and lymphocytes the pyelographic injection of the renal and perirenal lymphatics fre quently associated with forms rupture and pyelovenous reflux and the control of the condition by repeated intrapelvic lavages with sclerosing solutions support the surmise that there is a lymphatico unmary fistula at the forms of the calves

The control of chyluna can be accomplished without much difficulty by repeated intrapelvic lavages of silver nitrate solutions through inlaid catheters but the cause of urinary stass must be removed and fat must be eliminated from the diet after such lavages. The success of such management depends on the extent to which the predisposing and crotting causes can be eliminated.

JOHR A. LOET M D

Solomon, S.: The Treatment of Gonococcal Arthritis with Sulfonamides and Artificially Induced Fever. Am J. Syph., 1945. 29, 567

Twenty three cases of drug resistant gonococcal arthritis are reported. Of these to were treated with sulfonamides and artificial lever in the hyper therm with the following results 4 were cured and the remainder showed either considerable or partial improvement. Fifteen were treated with sulfonamides and fever artificially induced with intra-enous typhoid vaccine with the following results 6 were cured 6 were either considerably or partially improved 3 were not improved and 2 of the last group were subsequently treated in the hypertherm with good results.

The results with both of these methods were encouraging. The use of the hypertherm is preferable to the use of vaccine. The most important conaderation however is early treatment. Hence if the hypertherm is not available combined vaccine and sulfonamide therapy should be instituted without delay. It is emphasized that specific therapy does not supplied the regular methods of management of arthritis, which include bed rest, special diet and physiotherapy. Specific therapy is used in addition to those and results in a much greater percentage of cures and in the restoration of joints to useful fine from Joint A. Lorr M.D.

Koch R A Haines, J S., and Hollingsworth W Y: Penicillin in Gonorrhea Treatment and Control J Am M Ass 1945 129 491

The authors results do not justify the behef that penicillin is an easy infallible cure for genorrhea Penicillin will cure most cases of genorrhea but cure is not necessarily accomplished by the first course of the drug or by penicillin alone Supportive treat ment, such as pyrotherapy and sulfonamides is necessary at times Penicillin failures are frequent enough to warrant diligent search for genococci following medication, for absence of clinical symptoms is not proof of cure.

Two groups of cases one under hospital conditions for 8 days and the other under clinic conditions for 9 weeks are compared. The minimum hospital criterion of cure was two negative consecutive cultures obtained by prostatic massage the last one being made at least of hours after completion of the medication and preceded by the provocative passage of sounds. The minimum clinic criterion was three consecutive negative cultures with one week between cultures. The taking of one follow up culture is not conclusive or adornate evidence of cure.

Fourteen per cent of 485 patients treated with an initial course of 200,000 units of pencillin were not cured. Patients with gonococcic epididymitis or prostatitis responded as well to pencillin therapy as those without such complications.

Penicillin is unquestionably the most valuable therapeutic agent thus far available for the treat ment of gonorrhea. The medical profession must be awate of the limitations of penicillin therapy the possibility of producing a carrier state and the social factors related to the spread of the disease.

DAVID ROSENBLOOM M D

# SURGERY OF THE BONES, JOINTS, MUSCLES, TENDONS

CONDITIONS OF THE BONES, JOINTS, MUSCLES, TENDONS, ETC.

Bowden R. E. M: Muscle Changes in Denervation and Re-Innervation. Brit. M: J 945 1 487

The muscle changes in denervation and re-inner vation are considered from the point of view of histology electrical reactions electromyography and

the treatment of paralyzed muscles.

In the matter of structural changes, in the early stages (1 to 3 months after denervation) there is a loosening of the compact arrangement of the muscles and an apparent numerical increase of the nuclei there is some stasis of the blood the nerve fibers undergo. Wallerlan dependance on the empty Schwann tubes and empty motor end plates remain. After 3 months the muscle fibers atrophy and are replaced eventually by fat and connective tissue ghosts of muscle fibers a few capillanes, and the larger nerve trunks may be seen surrounded by fibrus tissue a few scattered connective tissue tubes containing granules may be all that remain of the muscle fibers. However the changes are Dre

dominantly those of atrophy and not of degenera

tion, and up to one year after denervation it is

possible to expect a fairly good degree of functional

recovery from then on the prognosis deteriorates.

and as a rule after a years the prospects are exceed

ingly poor There are, however notable individual variations arepsis, age, mobility of the limb and physical therapy influence the rapidity of the changes. With repart to the electrical reactions, Erb's reaction of degeneration develops, faradic stimulation is lost and the threshold to galvanic stimulation with loss of contractife substance and may finally disappear altogether if a trophy is advanced. The fallure

to elicit a galvanic response in the absence of edema indicates serious change in a muscle.

On the subject of electromyography the author

On the subject of electromyography the author notes that for about from twelve to twenty-elght days after denervation there is no recordable electrical activity in human muscle on attempted movement or at rest from twelve to twenty-elght days after denervation, however, fibrillation does occur thus is aboven by rhythmic, fine spikes on the tracing, which are totally unrelated to attempted voluntary contraction. Fibrillation persists as long as any contractile denervated fibers remain or until re-in nervation is akidne place.

Ferralic stimulation is useless the denervated muscle however responds to galvanism, and this therefore one method of treatment. Electrotherapy not only should be regular and adequate but should be join as soon as possible later injury. Physical therapy is also of value in the prevention of contextures in the paralyzed muscles daily movement throughout the whole range of the foliats of the limb should be carried out, and splinting of paralyzed

limbs is never done to obtain immobilization rales there is a fracture or an unhealed wound,

However whatever the treatment, the degree of functional recovery will depend on the nature of the lesion in the nerve When the tranms or lesion to the nerve has not been sufficient to intermed the supporting tissues of the nerve, although the transhas been sufficient to cause complete peripheral degeneration of the arous, good powerful independent muscle action may be restored but the pattern of innervation will be alightly abnormal. When how ever the nerve has been more seriously damaged there may be partial disruption of the Schware tubes and scar formation, then there will not be as even advance of reveneration arous and some or manent weakness and atrophy may be expected. Is complete division of the nerve no recovery on falls place without surviced intervention, which should be undertaken as soon as noesible. Even so some son there will result at the suture line, with unavoidable confirmion of the arons at this point, the number of nerve fibers reaching the end organs being thus diminished

Motor unit action potentials may precede rem-Motor unit action potentials may precede remtal observations in balated Instances, nevertheless to occur. Still, the finding of both fibrillation and motor unit action potentials indicates a partial or recovering degenerative lesion of the lower motor recovering

A good functional recovery is possible wills the electrical reactions are still abnormal.

JOHN W BRIDGAR, M.D.

Jackson, E. C. S., and Seddon, H. J.: Gairasher and Denervated Muscle Atrophy Brit. II J 1945, 485.

The results of electrical stimulation in the treat ment of lower motor neuron lessons in general war rant the formulation of certain conclusions

1 Muscle atrophy begins very soon after denervation and at first proceeds rapidly then it gradually slows down as the time after denervation

2 Interstitial fibrods is a constant feature of denerration atrophy and it follows that the great the atrophy and the fibrods the poorer the dimain functional recovery. It follows that if atrophy and be prevented or controlled there is a greater hishood that recovery will be satisfactory.

3 As yet there is no evidence that fibresis is irreversible. The treatment to prevent it should be started as soon as possible after deneration and continued until re-innervation has occurred.

4. The precise nature of denervation atrophy is still unknown. Disuss and a consequent impairment of nutrition undoubtedly play an important part.

Fibrillation has been regarded as an important factor in tiring out and causing atrophy of the de

5 It has been conclusively shown that muscle wasting can be controlled to a very considerable extent by repeated electrical stimulation with a stimulus of comparatively long duration Galvan sum has several disadvantages but it is the only type of stimulus of long duration generally available it was used in the investigation.

6 The treatment must be intensive both in the strength of the stimulus and in the number of con tractions at each session and it must be continued over a long period to be effective.

7 Galvaniam is of greater value in the prevention of wasting when it is applied early. It has been re ported that even the most intensive treatment did not altogether prevent atrophy

8. In the treated muscle the muscle fibers remain comparatively large. The interstitual tissue does not increase to any great extent and if reinnervation occurs, functional recovery is good. In untreated muscle the fibers shrink rapidly fibrous tursue appears between them, and recovery is poor

The rate of wasting in man after denervation is unknown. Adequate stimulation is limited by the large size of many muscles and other factors. This article describes the end results when 164 patients were examined in pr of whom it was possible to obtain readings with sufficient frequency to be of value Of these 54 were suffering from complete nerve lesions The results are based upon the find ings in these 54 cases Ulnar paralysis was present in every case in 18 per cent of those treated with galvanism and in 20 per cent of those not so treated there was also paralysis of the muscles of the hand supplied by the median nerve.

thalf of the cases were treated with galvanism and the other half without galvanism. Five charts are presented which show that in each period up to 400 days there was a steady loss of volume in the un treated muscles the rate of loss gradually diminish ing until after 400 days when there was little change Galvanism was not effective during the first 100 day period Galvanism was almost completely effective in preventing wasting at all other times. There is no doubt that the volume of the hand is better main tained when the retarded muscles receive regular galvanic stimulation.

The beneficial effect of galvanism is most notice able early rather than late after denervation. It follows that the earlier treatment is started the better the result. Galvanum at best prevents a de crease in the muscle volume. It follows that what ever has been lost from delay cannot be regained During the first 100 days, galvanism does not pre vent wasting it only retards it. Without galvaniam, wasting proceeds faster in the first 100 days than at any other time. It is never too soon to begin gal vanic stimulation. If the paralyzed part must be enclosed in plaster windows should be cut to permit carly application of electrodes to affected muscles

The cases in this study were treated six times a week. Recordings were also made in cases treated three times a week. In addition recordings were made when there was considerable variation in the technique The good results were in direct propor tion to the amount of treatment. Calvanism is of real value and success depends largely on the fre quency of treatment. The treatment consisted of the application of 90 stimuli per day for 6 days a week The stimuli were strong enough to produce a brak contraction They were given at the rate of 30 per minute with an interval of 1 minute between each group of stimuli to permit recovery from RICHARD J BENNETT JR. M D

Gootnick, L. T : Solitary Myeloma; Review of 61 Cases. Radiology 1945 45 385

The prognosis of solitary myeloma is much better than that of multiple myeloma. Judicious irradia tion produces relief of the symptoms and prolongs

Sixty-one cases in the literature are reviewed of this number 2 were the author's The average age of the patients was 50 years. The ratio of males to of the patients was 2 to 1 The ilium femur humerus and thoracic vertebrae were the most common sites in volved. The chief complaint was a localized pain gradually increasing in severity Pathological frac ture under increased stress and strain or trauma was frequent. A palpable mass was present at times Solitary myeloma did not produce a generalized weakness and anemia as seen in multiple myeloma Hyperproteinemia, renal damage, and low blood pressure were rare.

Roentgenologically there are two types of solitary mycioma. The first resembles, and is frequently interpreted as a giant cell tumor. The lesions are cystic and trabeculated within the medulia of the long bones or pelvis the cortex is expanded and pathological fractures are frequent. The accord type is characterized by bone destruction. The pathology in both types is plasma cell myeloma.

All types of therapy have been tried Fort; three cases were treated by irradiation following blopsy and curettage. As many fields as possible were used and the dose was fractionated from 700 to 500 r per portal for a total dose of from 1,000 to 3 000 r The course of therapy could be repeated whenever nec essary Relief from symptoms was obtained in all but 2 cases. In 29 cases recalcification was demon strable with x rays. Generalized spread occurred in

In this series 27 patients survived and 16 died. Of 15 who died (1 died of a cardiac lesion) all but 1 lived more than 21/4 years from the onset of the symptoms. The average duration from the onset of symptoms was 7 years, and the lapse of time from hospital admission to death was 3 years and 9 months for the solitary myelomas in contrast to 14 months for the multiple myelomas.

Most authors believe that the duration of life is dependent on the transition of the lesion from the schitary to the multiple type f my l ma. Solitary lesions tend to be being and edit for years whereas multiple lesions are malignant. Markies D. Salis, M.D.

Koch S. L.: Injuries of the Hand. Q Bull Verthrest Unro M School 1945 0 265.

Simple principles of treatment of hand injuries, early and late are concisely reviewed and pointedly illustrated

Immediate cleansing of the area surrounding the wound, then of the wound itself, with some water.

wound, then of the wound itself, with soap, water and salme solution prepares a clean field where restraint in débindement is essential. Only if the wound can be closed for primary healing (by skin graft or pedunculated flap if necessary) can deep structures safely be repaired. Fractures may be reduced, but no nerve or tendon suture abould be done without assurance of wound healing by primary auton. Concerning local chemotherapy with sulfonamides the author quotes Meleney's report and War Depart ment Directives which indicate that extensive clinical trail has proved its ineffectiveness.

Satisfactory late repair of compound injuries rests on three basic requisites which must be faithfully ful filled in spit of all pressure on the argent for speciaction (1) superficial a d deep tusses must be free of infection (2) all inflammatory reaction and aduration must be gone from the affected area and (3) the general condition of the patient must be optimum for prompt healing of extensive served wounds. The period of walting for these condition to be realized is important and should be utilized to bring all factors in the final effort to an optimus The normal status of the circulation, free joint motion and good muscle tone are emental to a satisfactory end result and all are stimulated by active motion in a warm water bath. Spirits are needed to support paralyzed muscles and prevent stretching and can also be used with gentle traction to overcome contractures already present.

A normal soft thance covering for the injured pain must be prepared to replace this near which is a self-causes contractures and cannot be used to over deep structure repairs. Combined nerve and tendinglary is frequent and repair should be undertake as a single project to conserve tissue and time. Cur rent literature on this subject is cited.

Essentials for success in this type of surgery are that the wound heals by primary union a minimum

Fig. Ventitator fan injury of the right hand. The therax and bypotherax mades were severely lacerated, the nettearpopolategoral joint of the thomb as laid open, and the ulnar nerve and blood venuchs are avulsed with flap. The loder and middle fingers are sulmost completely valued at the premisal Inter palalargeal joints. Immediat cleansing, carising of the ragged and tom these reair of the joint capsale of the thumb, sturne of the ulnar nerver, and choure of wound without drainage were done. Left, Immediately after injury Right, tiprinary dressing, 6 days later.

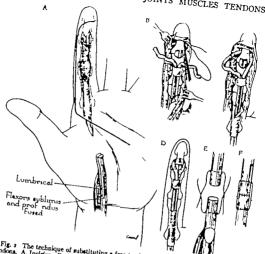

Fig. 2 The technique of substituting a free tendon graft for hopelessly injured flexor tendons. A Incision. B After the fibroped dexor tendon have been existed, free grafts are drawn through the carefully preserved tendon sheath and a suide sature is carried around the distal phalant through a bust witned made with a shapered ancurpen around the distal phalant through a the most bust and the statement of the two tendons are smoothly united the two grafts are drawn tant, by tension on the tendon first drawn through the united, and the line atture comes to the the midding on the dorsam of the distal phalant. D Fine silk entered the tendon graft and the stump of the production help to make the attachment of the profundation of the provincial segment of the flexor profundus. Incision in the finger is closed one suture of the graft to the profundus is carried out.

of inflammatory reaction to surgery is incurred and that the postoperative wound be kept at rest so that sutured nerves and tendons are relaxed until firm union has taken place

Increase may be planned to include excision of an old scar and thus avoid multiple scarring. Cosure over repaired nerves and tendons must be made by names of a reflected fland tendons must be made by the state of the state of the scar and subcut account state. Continuity remains uninterrupted over the deep suttent of the state over the deep suttent of the state of the scar and tendons only with account customer of the scar and tendons only with a proved to initiate scarring and adhesions and thereby nhibbit free gliding on which normal function depends.

Tendon grafts are useful to bridge separations particularly of severed fector tendons within the digital sheaths and may be taken from the long extensions of the foot uninjured portions of the flexor

sublimis or the paimans longus. Problems arising in the use of tendon grafts are discussed and the technique used is described and illustrated

It is best to remove the distal fragment of the flexor profundus and fix the graft directly to the phalanx. To facilitate freedom of movement, the graft is carefully discerding discounting the same companying thin layer of arcolar tissuch an accompanying thin layer of arcolar tissuch an adequate incision is used to avoid traumatizing the graft in securing it which reduces the fibrous reaction and subsequent scarring.

The tendon is held in place on the palmar surface of the finger by a part of the digital fibrous sheath or by a new annular ligament made from a free slip of tendon. The degree of tendon at which the graft cult to describe but it should be suffigurent is did of the normal physiological state this may be obtained by attaching the graft snugly when the wrist

and fingers are maintained in the fleved position. Postoperative immobilization must support the tissues with a minimum of tension at the sature line until firm healing occurs, usually in from three to four weeks. Too early attempts at motion pro-

oke additional inflammatory reaction therefore gentle active motion is withheld for from two and one half to three weeks. Paralyzed musicas need continued protection against stretching until nerve regeneration is complete in order that the integrity of their function is maintained.

FRANCIS E. BREMUTCER, M.D.

Platt, A. D: Post Traumatic Para Articular Calcifications and Ossifications of the Ankle. Ass. J. Reest. 045-54-545.

Post traumatic calcification of a foint is important and frequently encountered in military personnel. Although calcification of most joints has been described little or no mention has been made of it in the ankle foint.

The etiology and chemistry of para-articular calcifications as well as anatomy of the askle joint are discussed. In most instances, trauma is the predis posing factor. Immediate reentgen films may reveal only a soft tissue swelling. Serial roentgenograms serve to explain and sid in making a final diag noise. Within 30 of a weeks following the initial in jury linear calcification may be seen parallel to the posterior is post first the anterior superior talus, or lateral malleolus. Calcification may be seen also in the interactions us space. There are two types of calcification evolutive, which appears fursy and has hazy margins with varying degrees of opacity in the adjacent connective tissues and stabilized which is a mature contracted, well defined density

Treatment is conservative immobilization and physical therapy. Sedation may be employed for pain. In the military services, it is wise to excuss these patients from marching and give them office positions. In severe instances anesthetic injections have been used with good results. Radiation therapy also has been used with storonible results. In most cases, full function of the antile in ever restored, and calcification may penaliz and be followed by fusion. Although there have been reports of cases of spon taneous regression of calcifum, they are very rare.

MAURICE D SACRE M.D.

Horn, G. E.: Acute Ischemia of the Anterior Tibial Muscle and the Long Extensor Muscles of the Toes. J Bens Surg. 1945, 27, 615

The author presents 2 case reports describing a peculiar type of vascular disturbance, a localized ischemia of the anterior tibial muscle and the long extensor muscles of the toes.

extensor muscles of the toes.

The characteristic clinical symptoms and findings are sudden onset of severe pain in the anternor portion of the leg rapid development of swelling over the anterior fascial compartment, mild to intense evithema and glossiness and slight to complete perponel herve involvement.

The hist logical changes are identical to those occurring in Volkmann's ischemia. The vaculm change is a forests of the media, adventitia, and the periarterial tissue of the anterior tibial artery and ensuing occlusion

The pathogenesis is obscure, but may be explained by repeated overwhelming physiological demoke upon the anterior tibual artery for cample, dury military drill. Because of the anatomical array ment, the musculature of the anterior fascial one partment is particularly vulnerable to circularly disturbances. Idiopathic clawfoot may knew the origin is unsufficiency of the anterior tibul array

with fachemic contracture.

The treatment consists of early block of the labor sympathetic ganglis and early complete verial incusion of the anterior facial cruis. Arteretory advocated by Lenche, should be performed if piletion does not return in the anterior tibkil artery fix authors state that Lenche believes that the skill crated artery becomes a diseased sympathetic serv, inducing vasoconstriction in the collected network. He has demonstrated the increase in the collection circulation following resceint on the diseased story

oral fractures, and 8 moderately comminated fern oral fractures 2 had oblique fractures and 1 had a transvene fracture. Each pattent received approx imately three million Oxford units of penicifilin either before or upon entrance to the hospital. Twelve hours had elapsed before initial surgery was lone. Reparative surgery was instituted 9 days after the injury. The soft parts beaked in 4 or 5 days Callus was noted in 5 5 weeks and bony union ensued after 11 weeks. Good results were obtained in 38 cases.

Group 3 consisted of 12 cases in which wound closure was performed by the authors without the use of penicillin. In addition to the general treat ment, there was delayed primary closure without draining in this small group. Initial surgery was performed in 15 hours and reparative surgery in 6 5 days. Callies formation was noted in 6 weeks and firm bony unfort in 10 weeks. Good results occurred n. 11 cases and a fair result in 1 case.

Group 4 consisted of 18 simple femoral fractures, 4 of which did not respond to skeletal traction. These were subjected to open reduction, proper alignment being maintained with metal plates. The results were rated as good in all of the cases.

In conclusion the author maintains that penicillin and blood are of paramount importance in the prevention of sepsis and local infection. If however adequate preliminary surgery is not performed they alone are not a panacra. Reparative surgery of the soft issues consisting of secondary debridement and closure instituted between the fifth and tenth days, enhances wound bealing. The author also believes that the majority of femoral fractures can be treated by acketal traction when indicated he recommends open reduction of simple as well as of compound fractures. Sorondo, J. P., and Ferré, R. L.; Knee; Fracture of the External Tuberoeity of the Tible (Redilla fracture de la t. beroeidad externa de la tibla). Res is méd especia 945 59 1 57

Fracture of the lat ral tuberosity of the tibla is caused by a violent valgus devastion of the knee generally accompanied by tomon while the knee is in extension and slight fiection. The chief fracture line is directed outward, downward and forward There may be secondary fracture lines.

The symptoms are pain at the site of the fracture, loss of function, swelling bemarthross, and excesavo lateral mobility. The reentgenogram shows the fracture line and fragments. The Internal fragment may not be visible because they are made up of joint cartilage. Surgical treatment is Indicated in all cases in which the joint nutrice is involved. The operative technique is described in detail and fluated with photographs and nontgeogram. Absolute ascepais in necessary ordinary surgical ascepts is not sufficient. The fragments must be true in place by some forcum material, such as a safe, acrew or a bolt with a nut on each end. I place cast is kept on for 3 or 3 months, after which master and active and passive mobilization of the bare a begun. After 3 or 4 months the patient may safe

with a cane if the x-rays shows solid bone called Within the past 21/2 years the author has operated on 8 cases. The late results cannot be reported by cause the time has been too short but the early results show that the disadvantages of operative compared with nonoperative treatment are the danger of infection, and necross of the fragments These can be prevented by the strictest ascre-The advantage of operative treatment is better reduction There is no danger of postoperathe rigidity as the internal lateral ligament and the cruciate ligaments are generally loosened by the trauma which caused the fracture. This cause a certain degree of lateral instability of the knee bot, on the other hand it favors mobilizatio when the AUDREY G. MORGAN M.D. cast is removed.

### ORTHOPEDICS IN GENERAL

Woolley P V., Jr., and McCammon R. W: Boar Growth in Congenital Myredems. J Public S. Louis, aux 7, 70.

The authors state that the chronologic appearant of ossification centers is a useful index to thyrid function in infancy but is too slow for use in the control of therapy in the young cretin. Normal lacer bone growth is suspended in the absence of the roxine, and roentgenologically visible changes occur within three weeks of the beginning of the admintration of thyrold extract. A curve of the some growth rate of the radius during the first two years of life is used as a standard for comparison that he radial growth rate in cretins before and during the administration of thyroid extract. Dense calculation at the epiphyseal plate, absence of carpal book and short radii are the roentgenologically recognit able stigmata of cretinism which are apparent before the clinical picture is clear-cut.

The findings in 3 patients from 2 to 4½ mostless age are described and in 2 cases correlated all a rays of radial growth resumption during three cartact therapy. Radial growth i thee case initially more raps I than the established nors, let levels off once the average growth is attained before my distance of the case of the case

This information provides a means of accurately regulating the thyroid treatment of cretic by

conthly x ray studies, and of establishing the diag sats of cretinism in infants under 2 years of age

## SURGERY OF THE BLOOD AND LYMPH SYSTEMS

#### BLOOD VESSELS

Freeman, N. E.: Secondary Hemorrhage Arking from Gunahot Wounds of the Peripheral Blood Vessels. Ann. Surg. 1945. 22 631.

Secondary hemorriage following gunabot wounds in the first world war was a common complication. Although present methods of districtment, insocial lastion, and chemotherapy have resulted in arriting reduction in the frequency of this complication, the occasional occurrence of severe bleeding often with disastrous consequences, still make this problem an important one. The author arrives at the following conclusions Insofar as his experience was concerned.

The incidence of secondary hemorrhage in 2,168 cases of gamshot wounds of the neck and extremities was 1 to 5 per cent. Of the 23 patients, 15 hied myounds of major blood vessels. The present study is based on an analysis of these 15 cases.

Laceration of the arterial wall, rather than complete severance, was found in the 13 petients whose wounds were explored. There were 3 deaths in the group. Two patients developed gas gangeme and if of these died. Ligation of the femoral artery resulted in ischemic gangeme requiring amputation in r case. Recovery took place in the remaining patients.

A listory of severe or recurrent hemotrinage in the forward area, or the presence of severe seems on admission, is indicative of injury to a large blood vessel. Secondary hemotrinage is to be anticipated in cases with these findings. In spite of a demon strated large opening in the main arrey of the extremity the peripheral pulse was normal in 6 cases reduced in a and absent in only a patients. Perfarerial bematoma was found in 4 individuals, but pulsation and bruit was present in only sof these. Perpheral edema or diminished sensation in the distal parts of the extremities was present in three-quarters of the cases with lacerations of the blood vessels of the extremities.

One case of rupture of an artenovenous aneutysm of the neck is reported. In a second case of second ary hemorrhage from the neck, the bleeding, which was definitely venous in origin, was controlled by suture of the tissues over the bleeding point. Both national recovered.

In all patients the major artery was exposed by wide extension of the original wound. Sature of the arteral laceration was attempted on a occasions. It was apparently successful in c case. In the second case thrombosis at the suture line extended down word and countributed to the development of gan grene. In the remaining patients the artery was divided and ligated with No r achomic catgut. No untoward results were observed after the use of this absorbable supure material.

The injection of alcohol into the region of the paravertebral sympathetic ganglia was performed in 4 cases with good results. In a fifth patient, procume was repeatedly injected.

A small initial bemorrhage occurred in 7 patient before the severe blood loss which prompted operation. Attention is again called to this red signifas an "inexorable indication for exploration of the wound."

Eaton R. M., Czebrinski, E. W., and fmith, J L. Observations on Pulmonary Arterial Pressurand Peripheral Venous Pressure Influen-Arterial Blood Lots. J There, Ser. 1915, ir 339.

This contribution represents the first of a series studies concerned with polimonary and circuitary changes resulting from simple peripheral states blood loss. During experimental stakes by the authors on pulmonary lymph flow in what carrolled arterial bleeding was instituted, very consistent long changes, which were almost starting is their apparent import, were observed quite activities ally Pulmonary elema and pulmonary bemoving were produced at will by the simple removal a moderate to large quantities of blood from the formal artery the greater the blood loss, the praint the pulmonary damage. Insamuch as great and blood is such a common occurrence on the buffelds of the world, a study of the physiological factors involved in this pulmonary change exacts.

The authors first report the results of their experiments with a large group of dogs in which is per cent of the blood volume was removed, for it as thought that the loss of this quantity would sizekin a battle canualty. A second series of experiments will to per cent loss of blood volume was made to compare with an operative hemorrhage of about you can an everage human being. The methods of study are described in detail and the results are discussed at some hearth.

It would seem possible that the pulmonary cosgestion resulting from systemic arterial blood has b the result of increased permeability of the already endothelium, due to acute anoxia of the timed When the physiological events are reconstructed, as acute anoxla is apparent for many reasons. Breathing is noted to be rapid deep and forced an hangel has been produced and carbon dioxide concentration is increased With arterial hemorrhage, there is a true loss of blood volume and a decrease in available red corposcles to carry oxygen. The heart rate in creases in hemorrhage but cardiac output actually decreases. There is evidence that the circulation time is greater and that vasodilatation occurs Besides these factors, there are certain experimental observations which show that deep rapid, forced

time is safe. This can be ascertained only by careful observation at the time of compression

In the course of compression the limbs may be come cyanoid from proximal vein pressure. This is without dangerous after effects and may be counter acted by massage and warming. Canotid pressure may cause coughing from simultaneous vagus nerve pressure. If applied for a short time, compression does not cause painful sensations. If after a or 3 hours pain develops, it responds well to small does

of narrotics.

After the apparatus has been used it can be disassembled and the parts cleaned with alcohol and
packed away. The block, grooves, and globular nut
must receive particular care. The clamp is left
cemented in plaster but its grooves must be cleaned
well with alrohol.

To check the efficiency of compression, a sphyg mographic record of the arteries, such as the common carotid or subclavian may be made or digital palpation of the distal vessels carried out.

One patient completely recovered from an arteriovenous aneurysm after prolonged application of the compressor to the right subclavian artery His case is reported

In order to develop the collateral circulation, one must compress a single arterial trunk without disturbing the collateral paths.

Matas vessel compressor is unit for compression of the femoral artery immediately under Pouparts ilgament, as well as of the subclavian or carotid arteries. The proposed vessel compressor allows compression of nearly all the large arterial trunks such as the common carotid subclavian and femoral arteries, but it cannot be used for direct compression of the illucartery. When this vessel requires ligation the application of pressure to the femoral artery high under Poursat's allegament is recommended.

ROBERT R. BIGGLOW MLD

Whipple, A. O: The Problem of Portal Hyperton alon in Relation to the Hepatospienopathies.

Ann Surg. 1945, 133, 449.

This contribution is based upon experience and studies paned from the organization of the Spiken Clinic at the Columbia Presbyterian Medical Center in New York. In order to elucidate the pathogenesis, pathology diagnous and treatment of portal hypertension certain points in the anatomy and physiology of the circulation of the liver and subject are referred in detail.

spieca are reviewed in detail.

The amount of portal bed obstruction, and the type and site of obstruction are all variable factors in individual patients with portal hypertension. It is the discovery in the individual patient of these factors and their analysis that very largely determines the diagnosis, treatment and prognosis. Patients with portal hypertension may be divided into two main groups group I those having intra hepatic portal block and group II, those having extrahepatic portal block. In the first group the cirrhoses especially of the portal of Leannec type

are associated with portal block. The metral influence of the portal and arterial pressure while the lover provides an important explanation for the rise of portal pressure in portal circhost, so disexplains the variability of portal bypertenson as the criticoer and the presence or absence of garaintentinal hemorrhage as an accomposition of

portal hypertension. With regard to group II there are two types of obstruction seen in chronic occlusion of the nortal vein and its main tributaries. The first is a m placement of the vein or its main tributanes asis fibrous tissue with little or no canalization The second is a transformation of the portal reis at main tributaries, or the enveloping tissue into a cavernomatous mass of small tortnom vessels a process snoken of as cavernomatous transformation of the portal vein. In the first type of fibrous re placement there are two cannative factors. The most common is an organization into scar tisse of a thrombosis of the portal vein. The thrombosis may be the result of inflammation trauma, or present from without by inflammatory or neoclastic tesse. The second causative factor is an extension into the left portal vein, or proximal to it into the min portal vein, of the obliterative fibrotic process that takes place at birth in the umbiheal vein and dactor venosus as they empty into the left portal vein. The type of obstruction is rare but is seen in young children that begin at an early age to show ports block with splenomegaly and a Banti syndrome. The pathogenesis of cavernomatous transformation is not definitely known but it would seem logical that the etiology of this lesion is a variable oce

that the etiology of this lesion is a variable one. The collateral circulation in portal block has been classified as of two types, the "hepatopetals of the hepatofugale. When the circulation though the liver is unobstructed and the block is limited to the portal vein the blood may be shanted haven the hepatopetale collateral veins into the liver. In lesions causing intrahepartic block the bepatofught circulation shunts a variable amount of blood few the matterioritestimal tract and spleen around the

Both chronic intrahepatic block and extrahepatic portal block have been successfully produced in experimental animals. In the experimental samula and in many of the patients, portal bed block produces a fairly typical syndrome. This is true of the cases showing a splenomegaly whether the block s intrahepatic or extrahepatic. This syndrome conants of a variable secondary anemia, a leucopenia, a thrombocytopenia, a splenomegaly, and a tendeory toward repeated severe gastrointestinal hemorrhaps, most frequently associated with ruptured copiest cal varices. The liver may be cirrhotic or normal, according to the site of the portal bed obstruction This syndrome is frequently spoken of as Bantis syndrome It is the author's present concept that Banti s syndrome is the result of mechanical abstruction to the flow of blood within the portal bed In the cirrhoses there is a variable amount of portal

hypertension, determined by the amount of scar tissue in Glisson's capsule the relation of the prestame in the hepatic artery to that in the portal vem, and the extent of the hepatologale circulation. For and the extent of the neparotugate circulation. For these reasons aplenomegaly gastronicatinal hemory three tensors specimeness y sestimatement nemor rings [sucopenia, and thrombocytopenia are not mage recopenia, and unomocyopenia are not always found in the cirrhoses. This syndrome is not aways round in the critimoses and syndrome is not characteristic of the biliary and cardiac cirrhoses On the other hand if the extrahepatic portal block, On the other hand it the extranepatic portal block, from whatever cause, is sufficient to produce splenomegally Bants syndrome is nearly silvays specioniciany menus syndrome o neutry storage present, and a normal liver is usually found even in the cases of long standing

Patients with portal hypertension great enough to cause an enlarged spicen usually present leucopenia thrombocytopenia and secondary anemia of Banti a syndrome. There may be no history of gross gastro-Symmonic, Americanasy de no menory di gioca gastion intestinal hemorrhage, The differential diagnosis interinal nemorrnage ine differential diagnosis from other aplenomegalies is largely determined to the control of the control securate hematological studies. The site of portal block, as to whether it is intrahepatic or extrahe patic, can usually be determined by certain liver patic, can usually be determined by certain uver function tests. If the liver function tests are necessarily to the first state of the first state five it is safe to assume that the block is extrahe Patte. This does not determine the site of the certainepaire block, although the history or the age of the patient may indicate it. The author has been nable to determine the site of extrahepatic block at the time of splenectomy in more than half of his patients although recently he has been able to demonstrate the block by diodrast venograms and nenigenograms made during the operation at the time of determining the portal vein pressures

The therapy of portal bed block, both intra And uncapy of police we only the heart a hopatic and extrahepatic associated with Banti a yadome is considered in the discussion of treat ment. Three factors, the site of the block, the de Metic. Affect factors, the site of the proof, the use of portal hypertension and the extent and determine the content of the c Some of Portag hypercension and the categorian and competency of the collateral circulation determine the size of the spleen and the incidence of gastrointestinal bleeding. The two latter components of the syndrome are the usual indications for attempted ungical therapy. In the past, three lines of surgical states have been followed surgical states that the surgical surgical states have been followed surgical states and surgical states are surgical surgical surgical states and surgical surgical states are surgical states and surgical states are surgical states are surgical states and surgical states are surgical s Attack have been followed splenectomy the esactual maye peen ionowed spicinetions to co-called ablahment of a collateral circulation with omentopery and the ligation of tributance to the exophag pan and the upsation of all places is in the special panes, and the portal block is in the special panes, and the special panes of the portal places in the special panes of the portal places. with the removal of the spicen results in a permanent cone with disappearance of the Banti syndrome Unfortunately this site in the splenic vein is not a common one for portal bed block. However even mit the block in the main portal vein splenectomy of the for a warship time because of the provide relief for a variable time became of the temoval of a large area of the portal bed and until the portal by a range area of the portal root and united the portal hypertension builds up again. The effi Gey of omentopery is questionable. If the operation is done in the presence of a well established col historic in the presence of a west established the history venous circulation in the abdominal wall the months in the second state of the second seco statuts in a tew cases are encouraging out are properly due to Mature a clotts rather than to the surgeon s Attempts to ligate the tributanes feeding into the vents of the cardle and csophageal variess

have been disappointing Injection and congulation methods to obliterate the esophageal varies have nections to controlled the coopingest varies have not produced no improvement, since these methods shut produced no improvement, since these methods shut off one of the chief collaterals between the portal and on one or the contraction and increase the portal hyper systemic circulation and increase the portal ayper tension. The large number of patients with portal vein block and Banti a syndrome who had spience tomy but who continued to have recurrent gastrotony out who continued to maye recurrent gastro-integral hemorrhage challenged the members of the Spicen Clinic to seek a more effective and

The rare reported instances of attempts at the establishment of portacaval should attempt at any should be a stablishment of portacaval should be should the encountement of portacaval angular by sucure and the discouraging results signify the technical obstacles to its clinical application. The developoustactes to the cument approached. And develop-ment of the vitallium tube nonsuture method of ment of the vicamum care nonsucure mechanical blood versel anastomosis has afforded a new method blood vesser anastomosus nas autorued a new metnod of accomplishing either splemorenal anastomosus or portal vene caval anastomosis

Splenorenal anastomosis is capable of handling a Openotenal anastomosis is repeate or manually interesting of blood and has the peruliar advan tage of chainsting a sixable portion (estimated at tage of cuministing a sizable portion (committee at 40 per cent) of the total circulating portal blood volume by splenectomy. The authors coincil end younge by specifications are summer cannot be specification of the state of the sta sanatomoria of the spiente vein to the left renal vein. Renationions of the spicine vent to the relativest vent.

The facility with which an end to side anatomosis may be carried out with a witallium tube affords an alternate method to the sacrifice of a kidney exercises method to the sacrifice of a kidney. The serving the full length of the splent and pre-Reving the full length of the pilenic vels with min serving one into region or the spicine vein with min-imum trauma during spicinectomy. The spicine artery is ligated and the spicine is somewhat complicing of the blood. The spicine is somewhat complicing the spicine spicine spicine is through from the first of its blood. The spience vein is ligated just at its

primary dutal branching. The blood is then milked far proximalward in the vein and a rubber-shod clamp applied. Following removal of the spleen the stump of the splenic vein is opened triangulated with clamps, and irrigated with normal saline solu-

The left kidney is removed, but a maximum length of the main renal veln is preserved for the anastomosis, and a rubber shod clamp is applied as far proximally as possible. The stump of the renal vein is treated in the same way as the stump of the splenic vein and a proper sized vitallium tube is selected. The end of the splenic vein is passed through the tube, triangulated and everted over the end of the tube. The vein is held in place by a liga ture of silk placed behind a ridge on the tube. The intima covered end of the vitallium tube is introduced into the renal vein and a ligature is applied over the vein proximal to the ridge on the tube. A second ligature is used to approximate the renal vein anugly to the splenic vein near the end of the tube. The latter ligature prevents blood from penetrating between the two intimas. The clamp on the splenic vein is released and immediately following the clamp on the renal vein is released. It was necessary to resort to a veln graft in only 1 of the 5 CASCS.

The Eck fistula type of portacaval shunt has the advantage of size. An end to end anastomosis of the portal vein to the vena cava by the nonsuture vital lium tube technique affords an estimated blood carrying capacity from 30 to 40 per cent greater than a splenorenal anastomosis. In order to avoid the un desirable use of a vein graft it is necessary to mobilise the portal vein from its bifurcation at the liver to the origin of the splenic vein. The portal vein is mobilised, to protect the common duct and hepatic artery from injury and a rubber shod clamp is applied to the portal vein at the origin of the splenic vein. A transfixion ligature is placed around the portal vein at its bifurcation close to the liver, and the vein is transected distal to the ligature. The vena cava is mobilized from the level of the liver down past the entrance of the left renal vein to the upper level of the right renal vein and a clamp is placed but not tightened at this time. The portal vein is passed through a vitallium tube and cuffed over the end of the tube and ligated behind the holding ridge. The vein covered vitallium tube is now swung out from behind the common duct and over the vena cava, and a site for the anastomosis which will not result in angulation or compression of the vein is selected. Two nume string sutures of allk are introduced into the full thickness about the site chosen for anastomosis to form two circles the diameters of which are 4 and 6 mm. larger respectively than the diameter of the vitallium tube. A second clamp is placed at the upper part of the mobilized vens cave and the distal clamp is tightened to occlude the vens cava. A cruciate incision is made through the vena cava wall and the apex of each quadrant grasped with mosquito forceps. The veins are irrigated with

saline solution and the vitallium tube bearing the portal vein is advanced into the opening. The harpurse string suture is tied proximal to the ridge on the tube. To establish the blood flow the product clamp on the vens cave is released first followimmediately by release of the clamps on the porul vein and the distal vena cava, respectively

This article is based upon experience gained is the establishment of portacaval shunts in 10 case (s splenorenal anastomoses, and 5 portal vein to ven cava anastomoses) Convincing clinical evidence of portal hypertension should be procurable in the we majority of cases preoperatively One can accountly predict on the basis of liver function chemistry whether portal hypertension is due to intrahentic (portal cirrhosis) or extrahepatic portal bed bled. The variable origin of the coronary ven from the splenic or portal vein accounts for the presence of absence, respectively of esophageal varies in cogestive splenomegaly due to a block in the splene vela.

Splenectomy alone as a treatment for magestive splenomegaly should be limited to those cases of splenic vein thrombosis in which the connary vein arises from the portal vein, or if it arise from the splenic veln, to those cases in which the obstruction is dustal to its origin. At operation in case of congestive splenomegaly due to extrahepatic ports block, venous pressure readings are essential to de termine the obstruction sites in the splenic veh. normal reading from a branch of the superior meanteric vein and an elevated reading from a branch of the coronary vein of the stomach would indicate a block in the splenic vein and suggest that the coronary vein originates from the splenic ven distal to the site of the obstruction. This evidence would make splenectomy followed by splenormal anastomosis preferable to splenectomy alone. Is a case of congestive splenomegaly in which the superso mesenteric pressure is normal, the spicele von pressure elevated but the coronary vem present approximately normal, a solenectomy alone would be indicated. Venography following injection of diodres in a branch of the coronary vem is useful in maint ing the site of origin of the coronary vein. In most cases of cavernomatous transformation of the portal wein aplenorenal anastomous is likely to be the only type of portacaval shunt it is practical to use. It was found feasible in I case of atrests at the porter fissure in which the spleen had been previously removed to do a portal to vena cava anastomosis will a vein graft.

Every one of the 10 cases of portacaval sharib went through a successful postoperative convictcence. The interval following operation has been too short in some to judge the results. However, h 6 of the 10 cases the improvement has been so out standing that it justifies continuation of the procedure. The Eck fistula operation is better tolerated by the patient, in all probability because of less blood loss during the procedure.

### SURGICAL TECHNIQUE

#### OPERATIVE SURGERY AND TECHNIQUE POSTOPERATIVE TRRATMENT

Lovell, D L.: Skin Bacteria: Their Role in Contamination and Infection of Wounds. Arck. 945 51 78.

Investigations were carried out to determine the type and number of bacteria gaining entrance to the wound during the course of routine operation and their role in the infection of the wound.

To determine the number and type of organisms gaining entrance to the wound during operation

cultures were taken as follows

- 1 After proper skin preparation a sterile sponge, thoroughly moustened with isotonic solution of sodium chloride was rubbed over the skin. The saline solution was then expressed from the sponge into a sterile container. All this solution was cultured by the pour plate method. After 24 hours of incube tion, the number and type of colonies present were recorded.
- a Immediately after the increase in the skin had been made, towels were clipped to the edges to prevent, so far as possible surface bacteria from get ting into the wound. The wound was then irrigated with a small amount of isotonic solution of sodium chloride and the solution cultured by the method previously mentioned

3 After the primary object of the operation had been accomplished the wound was again irrigated and the solution cultured.

4. After the wound had been closed the towels were removed, and the final culture was made from

the surface of the skin

Although there is no accurate method of recover ing all the organisms in the wound or on the surface of the akin, the procedures used gave uniform re sults which were satisfactory for comparison. All operations were performed under bactericidal radi ant energy to minimize contamination from the air

Cultures were taken during 55 operations for inguinal hernia and during 115 operations of other types. Few organisms were obtained from the sur face of the skin immediately after mechanical and chemical cleansmg. Some of the cultures were ster ile, but of those which grew organisms the greater number presented the staphylococcus albus. Other bacteria, including the staphylococcus aureus, the escherichia coli, and a nonpathogenic fungus, were present occasionally in small numbers.

In the second culture, it was shown that in most instances a few organisms were carried into the wound with the skin knife. They were of the same variety as those obtained from the surface of the skin were relatively nonpathogenic, and belonged to the rendent flors.

The number of organisms obtained from the wound just before closure was considerably greater than the numbers recovered in the first tag of tures. This was probably due to the fact that the bacteria which gained entrance to the wound me tiplied during the time of operation.

A large number of organisms were obtained from the surface of the skin after closure of the worm This was thought to be due to the resident for rising to the surface and multiplying during the time of operation.

The number and type of bacteria obtained from the surface of the skin immediately after medicaland chemical eleansing did not vary greatly with the character or location of the operation. The number of becteria removed from the wound before down was greater in the operations for inguinal brok than in the other operations. This was thought to be due to the presence of numerous bair follows in this region which results in a larger rendert fan

During operations the skin should be considered contaminated at all times regardless of the propertive preparation. In closing the wound the towns should be left in place until the wound is closed to the subcutaneous fascia. At this time the surface of the skin should be considered much more contain insted than at the time the original increase in the akin was made. The towels should then be removed the surface of the skin cleansed with the antisepte solution, and clean sterile towels placed over the area before the sutures are inserted in the stin Stitch abscesses are best avoided by the additional precautions of carly removal of the suture and the avoidance of tension. Lucian J Fromon, M.D.

Starr I., Mayock, R. L. and Battles, M. G.: Convalescence from Surgical Procedures. Stude of Various Physi logical Responses to a Mile Exercise Test. Am J II Sc 945, t 713.

The aim of the authors investigation was to es plore the possibilities of finding objective methods of demonstrating abnormalities present in coavalecence after surgical procedures which would serve as an indication of the duration of the convalenced state and as a test of measures designed to shortes it. The authors believed that no abnormalities than acteriatic of convalencence would be demonstrable while the patients lay at rest, but they hoped that when the patients performed a task, abnormalities might manifest themselves. For this purpose as casy weight lifting test was devised which could be performed by the subject while lying in bed on his back and breathing from a spirometer designed to measure the basal metabolic rate. By this mean oxygen consumption could be determined without gas analysis and both the rate and volume of reco ration estimated from the spirometer record as ad

Oxygen consumption and volume, and the rate of respiration were determined before, during, and after standard exercise. The cardue output (belistocar

diogram) and pulse rate were estimated before just Oxform) and pure late were estimated below after and 5 minutes after the same exercise tter and 5 minutes after the same exercise

Ungley C. C. Channell, G D., and Richards, R. L.: The Immersion Foot Syndrome. Bril. J Surg 1045 33 17

Prolonged exposure of the extremitles to moist cold insufficient to cause theme freezing produces the well defined syndrome of immersion foot. In the natural course of a typical case of immersion foot there are 4 stages the period of exposure and the prehyperemic, hyperemic, and posthyperemic stages. During the first two stages the feet are cold numb swollen and pulseless, and pain is not a prominent symptom Within a few hours after rescue the feet become hot and flushed and the pulses are full and bounding. With hyperemia comes pain which is se vere, burning or throbbing in character and in creases in intensity for from \$4 to \$6 hours. Swelling increases with the hyperemia, and there is a rapid recovery of sensation from above downward until from 7 to 10 days after rescue, when a relatively sta tionary sensory picture is obtained Typically the sensory loss is of the "sock" or carpet alipper distribution. Further recovery of sensation is slow and is dependent upon the regrowth of nerve fibers. Areas that are to become gangrenous fail to warm, remain white or blue, and blister extensively. The duration of the hyperemic stage varies from a few days to months according to the severity of the case The posthyperemic stage may be absent in mild

cases, but in the typical case it is first manifested by a change in temperature of the feet, which become cool on exposure to mild cold. The feet remain cold for several hours and later may become permanent ly cold and "cold-sensitive." In some cases the feet are also heat-sensitive. Spontaneous excessive sweat ing of the feet is a prominent feature of the post hyperemic stage, and recurrent swelling tingling or shooting pain, and blistering are other complaints. In about two-thirds of patients with immersion foot the hands are also affected, usually less severely

When a limb is immersed in cold water the tem perature of the digits falls rapidly to within r to s of the water temperature. The earliest records of akin temperature in immersion foot syndrome have been made in from g to 12 hours after rescue. At this time the digits were already warm and within a few hours reached full vasodilation level. Once the hyperemic stage is fully developed the hand or foot. except for gangrenous areas, is warmer than the upper arm or thigh and the normal vasoconstrictor gradient is abolished Reflex vasomotor activity in response to heat or cold is absent, but returns grad ually In the posthyperemic stage the feet are al most habitually cool, and many degrees of reflex vasomotor activity may be observed. In the more severe cases there is complete failure of raflex vaso-

In the experience of the authors, the most signif icant factor in prognosis is the amount of damage to the peripheral nerves. A useful criterion is the extent of loss of sensation to cotton wool touches at the end of the first week, and cases have been subdivided into 4 groups on this basis

Grade A Minimal cases without interference or with transient interference with nerve function Grade B Mild cases with reversible nerve day. age.

Grade C Moderately severe cases with incren-Ible (degenerative) nerve lenous.

Grade D Severe cases with irreversible nerve is

slons and gangrene.

The essential cause of immersion foot syndrone is prolonged exposure of the limbs to cold insufficient to freeze the tassues. Contributory factors are malnutrition and exhaustion, and the relative immobility and continued dependency of the feet. Methesical interference with circulation as from tight dotsing or shoes is a factor Chilling of the upper part of the body from wind and wetness acts by reducing peripheral circulation. The disorder may arise a extremities exposed to prolonged cold with no mor damp than is provided by condensed perspiration.

The difference between frostbite and immerior foot is important but is not always dear cut. Is general, froatbite causes death of three by freezing and skin, being most superficial, suffers most, in inmersion foot there is prolonged chilling and inchess, which affects the tissues with the lowest belopping resistance namely nerve and muscle, most severly Even with irreversible nerve damage there may be

no loss of akin.

In the series of patients observed by the author, there were two groups of survivors from shipweek in warm waters. Edema of the feet may followerposure in open boats, in the tropics. This grow does not form a simple clinical entity Many of the cases resemble the peripheral vasomeuropathy of served after chilling. A number of factors are past ably involved such as immobility and dependency of the feet, unmersion in warm sea water semi-stuvation, dehydration, and the effects of sunlight.

Pathological material obtained from tienes affect ed with immersion shows that nerve and muscle fer most severely The peripheral nerves undergo a process of patchy Wallerian degeneration. Charge are most marked in the distal portions of the nerve, and fibers of small calibre appear to suffer more severely than large medullated fibers. The cinical and pathological evidence is in favor of the hypothesis that during exposure and in the prehyperesis stage intense vasoconstriction is the predominant feature. The combination of chilling and ischema gives rise to a peripheral vasoneuropathy The carly hyperemic stage appears to be due to release of stable vasodilator substances in the tissues, and once the effect of these has subsided, the hyperenia is saintained because of paralysis of peripheral vasors strictor fibers. The late vascular phenomena are more difficult to explain but it is assumed that the are the result of denervation and the subsequent in innervation of peripheral blood vessels, which may also acquire a sensitivity to cold analogous to that seen in the Raynaud syndrome.

In discussing the treatment of immersion lock confusion has arrien because methods which are of

value in one stage have been wrongly employed in value in one stage nave ocen wrongly employed in another. During the prehyperemic stage the authors advocate an intermediate course between cooling to advocate an intermediate course between cooling to 3 to 5 C as advocated by some and rapid warm into the degree to 3 to 5 C as advocated by others. The degree ing to 37 the as advocated by others and degree of warmth applied should be no greater than that a maniata spines snown be no greater than that seeded to permit relaxation of the arteries. While marming the body exposure of the extremities to a warming the body exposure of the extremities to a cool atmosphere (18° to 23° C) appears to be logical cool almosphere (18° to 22° C) appears to be logical and satisfactory. It is emphasized that efforts to and saturactory it is computation that curous to hasten the release of viscocontriction, whether by body marming, local marmth sympathetic block or body warming, wear warmin sympathetic bloca, or drugs may do harm unless steps are taken to control dugs may go narm unious steps are taken to control the degree of vasodilation when it occurs. During the hyperemic stage several methods have been sug the appetence stage several methods have been sug feated to limit the excessive exudation set up by a too rapid return of circulation Treatment by cooltoo rapid return of circulation treatment by cooling alone is often sufficient and should begin as soon ing atone is otten aumicient and should begin as sout as visodiation develops. The optimum cutaneous as vasodiation develops The optimum cutaneous temperature for prolonged cooling is 21 C. In the posthyperemic stage and for the late sequel of a pointyperemic stage and for the late acques of a cold-sensitive state a warm covering is demanded not only for the affected extremities but for the rest not only for the allectron extremities out for the real of the limbs and for the trunk. Smoking should be At the times and for the trunk Smoking about the orbidden if there is a tendency to vasorpain. Oc orman in there is a tendency to vasospiasar or capational therapy is of value. It is in this stage that sympathectomy or sympathetic block may prove of value in treatment.

Blackburn, G., and Rob, C. G.: The Abdominal Wound in the Field Eril J Surg. 1945 JJ 46 The treatment of an abdominal wound commences the treatment of an audominal wound commences included the first wounding and restriction is important. Rocardenography has been of little value in ab-Keentgenography mas been of little value in andominal wounds, especially with the type of machine dominal wounds, especially with the type of machine available in forward work. Of course it is apt to be available in forward work. Of course it is apic to be of value in the case of associated injuries which the or value in the case or associated injuries which the author believes to be of great importance over providing for their operative treatment concedental

viding for their operative treatment coincidents with or preceding the opening of the abdomen.

The authors do not believe that thoraccabdomic The authors do not coneve that thorsecondount also woulds are more grave than the purely abdominal variety but that in the presence elvice communications are also were the control of the commissancy vorting in the presence of perviction pleasing the results are apt to be poor. When the puctuons the results are apt to be poor when the fectum is intact they favor the use of the Murphy rectum is intact they involved the use of the attributed drip because with the usual venoclysis there is the onp occasio with the usual venocities there is interested anger of pulmonary edema resulting from the exdanger of pulmonary edema resulting from the ex-cessive administration of fluid into the vein after

When the large bowel is perforated the authors do When the large power is personated the authors do not subscribe to the dictum that exteriorization of not subscribe to the dictum that exteriorization of wounds of the colon, wherever located is the ac wounds of the coion, wherever societies is the accepted practice of at least, functional exclusion by epien piacine or at ions, innerional excussion of a proximal coloriony. Sixteen of the patients were colorion, and the patients were and a long and a long artists. a proximal coloriomy Sixteen of the patients were correction, with 5 deaths, and 57 by exteriorization, with 26 deaths. It is believed that routine orization, with 20 deaths at is believed that routine exteriorization of the right side of the colon is both extendination of the fifth side of the colon is both unnecessary and dangerous, and that suture is the fifth and a figure of the first many sums has the unnecessary and cangerous, and that suture is the simpler and safer procedure. This may even be the case in wounds of the splenic flexure where mobility that the safe of the splenic flexure where mobility that the safe of the splenic flexure where mobility that the safe of the splenic flexure where mobility that the safe of the case in wounds or the spience nexure where mount mation is often difficult and productive of shock. Of tration is often difficult and productive of shorts of course, these statements refer to young vigorous visions of the districtions. course, these statements refer to young victorous soldier patients at least, none of the deaths from soldier patients at least, none of the deaths from peritoritis in this series has followed surface of wounds pentonius in this series has tolkowed surface of wounds of the large gut. In fact in 1 case the wound of the intrapersoncal portion of the rectum was accom intrapersionest portion of the rectum was accompanied by multiple perforations of the small bond. paned or insurpre periorations of the amail power with three complete transections severe bleeding with three complete transcriping severe obecoming from the bowel and metentery, and eventration of some 18 inches of fleum, some 6 hours after wound some 18 inches or neum, some o nours after wound ing 3 et 2 feet of the ileum were resected and the ang yes y text of the neum were reserved and the rection was sutured (without colostomy) and the patient made a good recovery

literally wounds of the small intestine are the Naturally wounds of the annul intestine are the most numerous but they are relatively less neconstants. most numerous but tany are relatively in successful than the usual associated injuries (if one exclusion to the lines belongs and subsection). than the usual associated injuries (if one excluder injuries in one excluder kidneys and spices). In involvement of the liver Evineya and spicen) in fact, perforations seem to do well with single layered. tact, periorations seem to no went with single myerous affilier only in contrast to the large gut for which stuttes only in contrast to the large gut for which two layers are invariably employed. Drainage of the two is) era are invariantly employed. Drainage of the abdomen in these cases has little to recommend it. abdomen in these cases has fittle to recommend it is because blood, rather than intestinal contents is usually found in the peritoneal cavity. It has been the authors practice to drain the laparotomy round the authors practice to urain the saparotomy wound when there has been gross soiling and to drain the

peritoneum only when bile or feces in large quantity has contaminated it.

Kidney wounds are of leas concern at the forward station so long as the pedicle is not too severely involved when the pedicle is involved a nephrectomy may sometimes be required because of persistent hematuria.

The patient must remain in the field dressing station or the casualty cleaning station following laparotomy until his general condition warrants evacuation and the abdomen can be said to be fairly quiescent this usually involves to days or more. The danger of sitting patients up too soon after lanarotomy should always be remembered. The value of sulfadiasine (6 gm daily) in intravenous drip has already been stressed and results, as yet unpublished show sulfadiazine to be superior to penicillin in combating peritonitis. In the immediate postoperative period gastric suction and morphine are useful morphine (gr 1/4 every four hours) has always proved satisfactory as a sedative for the patient and his alimentary canal, and it can usually be discontinued as soon as the bowels act. This is rare before the fourth day, but it does not mean that an enema before this is always contraindicated. It may indeed be a helpful measure in a patient with an in jury of the small gut whose large bowel was loaded at the time of operation. An enema may likewise be useful as a preliminary measure before a rectal drip is started

As regards postoperative diet, it is, at first, fluid however, carried fluid charts have repeatedly shown that a pint or more of fluid per day is retained even with continuous suction. Nutrient fluids are there fore of use. Two hundred milligrams of ascorbic acid daily are given as well.

More than 50 per cent of the deaths occur from shock or hemorrhage within 48 hours. After this, the fate of the patient depends partly on the nature and multiplicity of his wounds and the interval between wounding and operation, the most important cause of death being pulmonary (bronchopneumonia pulmonary edema and embolism) Silent distention of the abdomen occurs guite frequently, but when not due to peritonitis it has not proved fatal in this series. Fluids other than plasma and glucose-saline solution have been employed—hypertonic saline solution for thorseosphominal wounds with severe laceration of the lung alkal for the patient with threatened anuria (a per cent or a per cent sodium bicarbonate) and blood for the anemia which so commonly becomes evident n the fifth to seventh day when dilution has followed the initial blood loss. Fresh blood, in this case is infinitely better than the stored variety

In the 210 cases of the authors material there was a mortality of 37 per cent, this figure closely paralleling that of other larger series quoted elsewhere. Disappointment in the results is most common in the first 14 hours after operation when the patient is described as dying of shock, and only an elucation of this condition is likely (in the view of the

authors) to make an appreciable difference is the mortality of abdominal surgery in the field.

JOHN W. BERGMAN, M.D.

De Waal, H. L. Wound Infection. Litebergh 11 J 1945 52 373

A knowledge of the fundamental physiological aspethological aspects of wounds will aid any suppoin his search for methods of promoting sound lealing. He should work in close to operation with his colleagues, the bacteriologist, physiologist, and a thologist and should concern himself as much with the study of infecting organisms and their effect or tissues as with the surgery and bedside treatment of wounds. The method of collection of material have wounds for bacterial investigation and the reschi is a series of cases are outlined and appraisal.

In both old and fresh wounds awabs should be taken both before and after saline lavation and se gical treatment. Prompt culture should be made for aerobic and anaerobic organisms in the respective swabs. Results from a series of 618 wounds to esamined showed (r) insignificant infection in iron wounds from o to 5 hours after injury (s) the proence of infection in fresh wounds similar to that found in old clinically infected wounds from 5 to \$ hours after injury, (3) infection by both bacteria and saprophytes in 88.8 per cent of the cases after 13 bours (4) a decrease of organisms in fresh would after cleansing and surgery, (5) that clinically misfected wounds already under treatment contained chiefly nonpathogens (6 and 7) a decrease in rospathogens but a proportionate increase in tissue is vaders particularly hemolytic streptococci, in the tissue swab after saline cleansing as compared to the findings in the swab taken before cleaning (comprehemsive swab) and (8) that subculture from primary fluid cultures gives an erroneous idea of the propor tions of organisms.

It is emphasized that it is the invading organism on the midding edge and in the deep tisses of a infected lesion which must be discovered and deh with rather than the organisma in the pas on its surface. This peccasitates the two swals, the second one taken after the pus has been removed with meticulous regard for the delicate healing tissue. But circularly the studies in these cases aboved that its staphylococcus albus, saprophytes, and other organisms were proportionately more prevalent in setting taken before lavage, while the hemolytic surspector us was more prevalent in waste taken after lavage, and the staphylococcus progenes was found in relief with the staphylococcus progenes was found in relief withey the sam proportionately.

It is postulated from bervation that the equiums in the deep theore prepare the exceptible issues for later Invasion by less pathogenic but one numerous invaders the latter which provides the latter which the part of the hardy but more pathogenic organization the provides and the provides t

discovered and proper therapeutic methods carried PAULE B CHARK, M.D.

Ether ener is the pest tolerated anesthetic agent. Euler provides practically all the anesthesis for major provides practically an the ancouncing our major cases in field hospitals. It was used too little at trace in meto nospitan. At was used too neder an first, but its use has increased in the surgically in portant group of wounds of the abdomen and thorax and in compound femur fractures.

In September 1943 deaths from sodium pento-In September 1943 Geaths from southum Pentor that were so common that the question of abandon that were so common that the question of anandon ing this agent was raised. Two correctable factors age to agent was taken the causes of these deaths were found present when the causes of these deaths were examined (a) its frequent use by completely trere examined (a) its frequent use by completely inexperienced individuals and (b) its use in case in inexperienced individuals and (0) its use in cases in which it was contraindicated. The advantages of which it was contraindicated. The advantages of sodium pentothal—its compactness and simple equipment the smoothness of induction the prompt equipment the smoothness of mouction the prompt waskening of the patient, the infrequent unpleasant after effects and the number of cases an inexpen atter energy and the number of cases an incapera-enced man can get by with have led to the decinon to continue its use and at the same time take measures to correct (a) and (b) The disadvan take measures to correct (a) and (b). The conservant tages of sodium pentothal are the facts that over donage is often difficult to overcome that its use is a constant to the constant and that the constant to the constant tages and that douge is often ormein to oversome that its use is incompatible with certain types of injuries and that incompatible with certain types of injuries and mai the fatal dosage varies widely in different individuals

penals cosace varies whosey in unicirem manyamase.

Pentothal destroys the senativity of the respirarentothat destroys the sensitivity of the respiratory center to its normal stimulus carbon dioxide tory center to its normal stimulus carbon dioxide

To maintain respiration a shift is made from the to maintain teapmation a sum to made from the normal driving action of carbon dioxide on the normal driving action of caroun distance on the respiratory center to the action of anorma on the respiratory center to the action of anoma on the chemoreceptors the carotid mechanisms in the neek Anoria stimulates respiranon under full peniohal anesthesia as well as under light anesthesia. When encourcing as wen as unusering a succession of the respiratory stimulation due to another is wrongly respiratory summission due to snown is wrongy interpreted and more penfothal has been given interpreted and more pentotrat has been siven deaths have probably resulted. In operations or condition one half hour consequences about the admitstance of the condition of the destin nave prooxoty tenuted in operations extered with pentothal and then the character of the teren with pentionial and then the character of the respiration is a helpful guide to the depth of another aspiration is a neutral gener to the veptus of ancastic size. The use of carbon dioxide to atmulate respira na. Inc use of carbon dioxage to summing e respiration depressed by pentothal is contraindicated because under such circumstances it causes de pression

The use of a 2 5 per cent solution of pentothal the the use of a 2 5 per cent solution of pentiums are routine administration of oxygen and frequent touring automorphisms of oxygen and irrequent observations of the pulse and blood pressure consti observations of the pulse and plood pressure consultate the acceptable practice in operations required tute the acceptance purcture in operations requiring from one half to three fourths of an hour. A shift to tom one mail to three lourns of an Bour A shift to ether is recommended if the operation requires more einer is recommended it the operation requires more time. The preoperative use of morphine may or may and the preoperative use of morphine may or may on the resorted to it may cut down the total quantity of pentothal needed but the author sugarity of the surface of the sur quantity of pentornal needed out the author suggests the supplemental use of 50 per cent introdu Sents the supplemental use of 50 per cent nitrous oxide and 50 per cent oxygen as a better means of accomplishing this end (tropine in a dose of 1/200 gr one of 1/200 per cent nitravenously just prior to another use of 1/200 commended to cut down varial reflexes. If larvin gr given intravenously four prior to ancestorism in recommended to cut down versal reflectes. If larry in the state of the recommended to cut down vegas renexes it tarys recommended to cut down vegas renexes it tarys are recommended to cut down vegas renexes it tarys recommended to cut down vegas recommended to cut down vegas renexes it tarys recommended to cut down vegas renexes it tarys recommended to cut down vegas renexes it tarys recommended to cut down vegas recommended to cut down vegas renexes recommended to cut down vegas intravenously is recommended

Pentothal is contraindicated when (a) the nations is suffering from a mornhine overdose. (b) when shock is present or anticipated (c) when cervical inflammation is present (inflammation in the region of the carotid bodies and sinuses causes sensitivation of the reflexes and may lead to sudden death) and (d) in the presence of was gangrene (since these toxins produce severe circulatory damage)

The use of pentothal is manally unwise (a) when the operative position interferes with the sirway (b) in intracranial survey because the operations are long and bloody, and the pentothal may came sudden resouratory depression and aports and (c)

in severe burns.

Its chief use in military medicine has been in short procedures for which relaxation is not needed

and the men are in good condition.

Local and regional anesthesia with procaine by drochloride and topical anesthesia with pontocaine or cocaine have been used for neurosurgical, maxillofacial, and minor surgical procedures.

Spinal anesthesia is usually a poor choice for recently wounded men, because their precarious circulation rapidly deteriorates under it. Its chief use is for emergency appendectomies and conditions unrelated to warfare.

Anesthesia was given in 15,025 cases, 1,628 (10.4%) being classified as abdominal injuries 1 tos (0.4%) as thoracic injuries with nieural imalment. and to8 (1.8%) as thoracoundning in

Of the men listed in the files of this thester as specialists in anesthesia, only 10 per cent were con tified by the Board so per cent had only the species sia training of an intermalp, and 15 per cent had from one to three months of special training is secthesia. The total number of physicians was so small that nume anothetists and a few come men were used under close supervision

Whenever possible the ablest anesthetists are sestened to combat sones as there the demands for native intelligence, judement, resourcefalses, and technical ability are greatest. In some instance men of unusual ability were used to train ansthetists to be sent to forward areas.

By accepting the limitations of sodium periods. that is, avoiding its use in badly wounded men and for providing relaxation, and using it for short pocedures in men in good condition a great reduction in the death rate which has been attributed to it im been possible. At the same time, its use his n-creased. Thus, sodium pentothal, together with ether and procuine, takes its place as one of the three most important anesthetic agents for me in military medicine and surgery

R. R. Bicklow M.D.

# PHYSICOCHEMICAL METHODS IN SURGERY

Her L. G : The Development of Roentgen Diag

This article is an extensive concentrated review of the development of roentgen diagnosis prominence is given to the role which contrast promised to sive the solution of the applicability necus pusyes in interior extensing the appureaming of this method. Two anatomical drawings of the Special or one mercane, two anatomical diagraphs of the human body duplay the organs made accessible to range transplant on and give the name mode of a ray cammation and the year that x ray examination annumeration, and the year that a ray community are first used for the diagnosis of disease of each of these organs. One plate shows contrast media. denier than itsue, the other shows media which are less dense than the surrounding tissue. A bibliog nay dense man one surrounding tosue. A ordinar raphy of 326 references helps to establish historical priorities.

A table enumerates 44 groups of anatomical parts A table enumerates as givens or anacounter parts and disease processes to which roentgen diagnosts is perticularly applicable Several conditions in which recurrency approache occess continues in minutes at ray diagnosis is of no avail are mentioned. Cer tan conditions can be diagnosed by other means

at an earlier stage in others the reverse is the case The absence of roentgen findings may be signifi ant in some conditions but meaningless in others and on the other hand the presence of x ray find lags may definitely indicate disease in some cases whereas in others they may not allow such con Cusions. (Examples of each of these conditions are CUIDDE (Examples of each of these conditions are given). The correct and incorrect use of the terms typical inding, and characteristic finding in discussed. All these facts and problems show that typical finding and characteristic mining and discussed All these facts and problems show that only the correlation with chinical findings and the way the contention with cumical minings and one knowledge of disease aspects make it possible for one to a seeing a state of a seeing as the content of a se the correct degree of emphasis with to arrive at the correct degree of emphasis with which a given x ray finding should be appraised As a seneral rule, a negative roontgen examination is much less agnificant than a positive one the most important exception occurring in chronic pul

Al far as the future of roentgen diagnosis is con cerned one may safely assume that practically no competing diagnostic procedure will replace this method. Usually the institution of other methods of the casalination of the c estimation, e.g., gastroscopy has given a further stimulus to roentgenology

The roenigen examination of the liver pancreas ad splen has not yet been perfected this presents n inviting goal to the ambitions radiologut. Body ction and soft thate toentgenography require further improvement. The popularization of rou the change has a regular intervals, not only of and estimations at regular interview and volvy with echost but also of the stomach (at least in case) with echication of control history of course with achierhydria and a familial instery of Perinc with achieving and a laminal matery of permitted and a laminal matery of permitted for the social importance of meta-adaptive of initial factors in to roentgenology The detection of initial lesions is

Great progress in diagnostic roentgenology is to be expected when electronic image amplification will expected when electronic image amplification will allow the production of incomparably brighter fluoroscopic pictures with negligably sugarifications of rays. Then motion and multiple pro-Jection studies will become a commonly used method and roonigen cinematography will no longer en and toenigen cinematography will no longer en Counter its present difficulties. This may contribute to a shift of nonligenological interest from anatomical to a court or recurgenous cast interest from anatomical festions to abnormalities in organ physiology and minor changes in the function of organs.

Arbuckle, R. K. Shelden C. H. and Pudenz, R. H.: Pantopaque Alyelography; Correlation of the rantopaque hyprography; curronnou or me Roentgenological and Neurological Findings.

The authors have analyzed 100 consecutive cases with a provinonal clinical diagnosis of protruded interventebral disc, all in naval personnel, of whom interventedrat due, an in navat personner, or whom any elegraphy 87 were subjected to pantopaque myeiography. Most of the men were between 20 and 30 years of ages and 50 per cent of them had had symptoms for age and 50 per cent of them had had a symptoms for only 6 months or less and 70 per cent for not more only o months of the commonest types of traums than one year. Inc commonest types or trauma associated by the patient with onset of the sympassociated by the patient with onset of the symp-toms were the lifting of heavy objects falls or slip-ping on wet surfaces without isiling

Preliminary filming of the lumbosacral area Preliminary mining or the immovancial area showed a list of the lumbar vertebrae either toward Move a list of the number vertexus created toward or away from the aide of the lesion in 47 cases loss of or away more the auto or the resident in 4/ cases or the normal lumbar lordotic curve in 27 cases and narrowing of the intervertebral cartilage space in narrowing of the intervented as Cartinage space in only 11 cases. However bony proliferation and nar omy is case. However your promuration and nar rowing of the cartilage space concerned were prescont, almost without exception in those patients who

The injection of 3 cc. of pantopaque in the lower lamber region was done usually with the patient prone on the tilting fluoroscope. Defects, even par prone on the titing moroscope. Detects even par tial obliteration of an axillary pouch or alight cleva the contention of all extracty pourse of engine cieva tion of a nerve electre, were searched for both with tion to a nerve sceepe were scattered for both with only cephalad and caudad, and spot films were on howing cepnated and caudad, and spot mais were made with the patient in the prone or even in the made with the patient in the prone or even in the oblique, position. Lateral views gave no additional in formation and were abandoned. At the conclusion

tormation and were acandoned. At the conclusion of the examination, pantopaque was pooled at the tip of the past and in 70 per cent of the oil was removed. With example, the time for the oil was removed. With example, the time for the main and the conclusion of the oil was removed. soont to bet cent of the whole myelographic properience the time for the whole mycographic procedure totaled 20 minutes. The authors observed ceture totaled to minutes are authors of some one of the state of the no toxic manuestations or signs or root unitation and no more headache was complained of than after

nutine lumber puncture
An operation was performed in 13 cases of this An operation was personned in 13 cases of this cases myelography was unsuccessful as Eroup of 5 cases in yeography was unnutreased octained assured the sacrates in which mye

lography was performed after successful opaque injection, the procedure was diagnostic of two protruded duscs in each of a patients diagnostic or questionably so of a single protruded disc in 54 cases of a disc and tumor in a case and of a tumor alone in 4 more cases-all proved at operation. Three more cases had clinical and myelographic evi dence of protruded disc but were not operated upon another a had positive myelograms but were nega tive at operation 7 were negative at myelography but showed a protruded disc at operation, and o more which were negative myelographically were not operated upon. All but I of the 81 protruded discs found were caudal to the fourth lumbar verte bra whereas of the 5 tumors encountered 4 were above the fourth lumbar and below the eleventh dorsal vertebra.

The authors were concerned particularly with the group of 7 cases which were negative at myelog raphy but revealed a protruded disk at operation, and found that all of these cases had a narrow subarachnoid space measuring 6 mm or less in diam eter as did also the 10 cases in which myelography was only questionably posit ve. On the other hand, there was operative confirmation of the roentren findings in all of the cases with a subarachnoid space wider than 16 mm. Even with a narrow substachnord space, midline or large posterolateral protrusion offered no myelographic difficulties. Failure to demonstrate the lesion occurred in patients having both a narrow subarachnoid space and a posterolateral protrusion too small to encroach either on the narrow column of pantopaque or on the adjacent nerve aleeve or pouch. No correlation existed be tween the interpedicular and subarachnoid widths.

The authors conclude (1) that roentgenograms of the lumbosacral spine without the aid of myedge raphy are of little definite help in the diagnosis of protruded intervertebral diacs (2) that pantopaging is a satisfactory medium for myelography because of the ample contrast, its lack of infrasing properties, low viscosity, and case of removal (3) that myelography should be carried out as an aki in Juagnosis and localization of single or multiple protruded discs, and in differentiating them from tumors and (4) that a negative myelogram in a patient whose substachnoid space measures less than 16 mm, does not preclude the presence of a protruded disc.

LILIAN DONALDSON M.D.

Schnitter M T and Booth G T: Pantopaque Myelography for Protruded Discs of the Lumbar Spine. Redislery 045, 45, 370.

Pantopaque, a radiopaque mixture of isomeric ethyl catera having a provisional principle constitent of ethyl idotophenylundecylate, and containing 30.5 per cent of iodine in firm organic combination was used astrifactorily by the authors for dagnostic myclography in 100 patients of a total of 313 with low back pain who were admitted to the surjical service of Bushnell General Hospital, Brigham City Utah.

Thirty of these 100 cases showed myelographic evidence of protruded intervertebral disc, matter in 3 patients, which was verified at operation. In other 5 cases, negative at myelography shorel protruded discs at operation, and a cases positive myelographically proved negative at openti-These 2 "false positives occurred early a the series and the visualized defect reported at first b evidence of an extradural mass, was on review for d to be due to the needles being left in place at the time of myelography an error of interpretation which was later avoided. Thirty-seven was the tree number of patients operated upon. A review of the premyelographic roentgenograms of the lumber spine in the 35 cases in which a protraded discusfound at operation showed a definite parrowing of the intervertebral disc in only 7 cases.

The technique of the procedure is recorded in tail. In more than 80 per cent of the case subjects to pantopaque myelography, over 80 per cent of the injected oil was removed at the end of the procedure. The authors stress the desirability of avoiding the auspected site of lesion as the site of injectors is cause injection and subsequent removal may be more difficult, the needle may strike the issue as enhance or distort it, or the needle itself may create defect as resorted.

A reaction occurred in a case in this series of or, manifested by symptoms of meningiams as elevation of the cell count, and in a matiance by its crease in the total protein in the spinal find, by rapid recovery occurred without sequelae. The degree of reaction, as gauged by change in the spinal find, by off the country of the country

The authors conclude that the verification of its presence of a protruded intervertebral does or obtained and the presence of a protruded intervertebral does not suppose the constitute of the constitution of a multiplicity of the lections make the use of myelography with parapaque (which they prefet to air or lupicolo) about papers (which they prefet to air or lupicolo) arising in indeterminate cases of low back pain with sential the constitution of the constitu

Gershon-Cohen J: Internal Derangement of the Knes Jointy The Disgnostic Scope of Soft Tesus Roentigen Examinations and the Vaccus Technique Demonstration of the Menicl. J. J. Reself, 1945, 54–335.

The value of the roentgen examination of the set timues and menuci of the knee has repeatedly been accessed.

It is not necessary to resort to special technique. The addition to the routine examination of the izer in the anterposterior and lateral views of the lore tudinal view of the patella and of blateral views the mensor will suffice. If any absormal soding are disclosed, further obluque and so-called later condylar views may be supplemented.

It is important that for the viewing of each room genogram one be supplied with a source of light which has wide variable intensities and that its

field of illumination can be regulated in size and need of immunication can be regulated in size and supplied to optimize visualization of the soft atructure

reaction developed within from 8 to 10 days the dose was increased to 150 r per field. The tumor dose approximated oo per cent of the total roentgers in air for the frontal lobe lesions 83 per cent for the temporal and parietal leasons and 72 per cent (76.5 per cent for children) for the occipital lesions survival rate in relation to the tumor dose is shown in Table L

The scalp tolerated the amount of radiation given very well. Regrowth of hair has been excellent even after 15 coo r

The mental state likewise, improved considerably co-ordination returned, and, although some aphasia or staria remained the mind cleared. In not a few of the cases the formerly-held responsible positions in society could be resumed.

The survival period depended to a certain extent on the type of tumor This is shown in Table II.

As may be seen, globlastoms multiforme had an almost reciprocally low proportion of survivors as compared with astrocytoma. Tumor doses in excess of 7 500 r will be required.

As a whole, definite clinical improvement was effected by roentren therapy of the malignant primary neoplasms of the brain and brain stem. No late degenerative changes have been observed which could be attributed to the irradiation.

T Larcons, M.D.

Fairchlid, G. C., and Shorter A.: Direct Irradiates of Cancer of the Stomach and Other Vhora Exposed Temporarily at Operation, Land. Load, 1945 140: 51

The authors report that the end-results of cir cinoma of the stomach are poor. In their emerience the percentage of 5 year cures has been from 1 to per cent and they believe that in most instance for ure is due to (1) late diagnoses of lesions that an isoperable. (a) incomplete surgery and (a) irradation Results with external irradiation have been pour cause of the necessity of avoiding injury of neighbor ing organs and the radioresistance of sastric temor Contact therapy covers small areas, at a doot of more than I cm., with little effect. Unequal distribution of irradiation is one of the faults of rados see implantation. The use of intracavitation irredution. as advocated by Livingston and Pack, has been in ited because of the fact that the tolerance don he not been established

In view of the poor results which have been tained in the treatment of gastric cardnoons, a seapproach -direct irradiation at the time of supply -to improve the percentage of 5 year cars, we deemed feasible. The advantage of this method s that neighboring organs are protected, also, the ismor dose may be high because radiation therapsis will not be worried by akin effects such as are are following external irradiation.

The authors used this method of irradiance as only on mustric lesions but also on cancers of the esophagus and of the colon. In all instances then was at the time of surgery, consultation between the surgeon the radiation therapist, the pathologist, and the anesthetist as to the best form of themps In radiation therapy, a units were used simplicators ly (one anteroposteriorly, directly to the lesion, and the other posteroanteriorly through the skm to the lesion) Farlier in the series, only I unit was used It was believed that with a units a greater and more effective tumor dose could be delivered at one tux and that it would not be necessary to give supply mentary external bradiation, as had been required when only I unit of radiation therapy was used

Fifteen patients were treated in the manner reported viz., 9 with cancer of the stomach, 5 with cancer of the esophagua, a with cancer of the coles, and I with cancer of the pancross. The tumor dow was 1,300 roentgens Of the 15 cases, 6 were palliative. No unusual postoperative radiation conplication has been observed.

The authors are of the opinion that this method is of value and that it is a reasonable approach to the problem of visceral carcinoma.

MAURICE D SUCK, MD

Goin, L. S., and Hoffman, E. F : Contact Rombre Therapy in Cancer of the Bladder As. Rende 945, 54 392

The authors have now modified the method of treatment of carcinoma of the bladder on which ther reported in 1940 and which consisted in marsuriality

tion of the bladder with subsequent contact irradia tion of the tumor by low voltage roentgen rays and are using instead suprapubic cystotomy under spinal anesthesia and reduction of the tumor to its bese by fulgeration, followed by direct irradiation of the tumor with one or two reopenings of the bladder for further irradiation.

The apparatus employed is a Philips-Metalix operating at 50 kv., constant potential, and 2 ms. with a shock proof tube 23 inches long and slightly less than 2 inches in diameter at its active end anode is 2 cm from the surface of the tube and the roentgen afflux is 1 143 per minute with a filter of 1 mm. of aluminum. This construction permits easy introduction of the tube, encased in a sterile stock inette and rubber sheath, through the cystotomy wound. The target surface distance used is 22 mm and a first dose of 5,000 r in air is administered to the base of the tumor. Most cases treated have had two cystotomies about 1 week apart, and have received a total dose of 10 000 r Only moderate sloughing followed the treatments and no severe hemorrhage, perforation or fistula formation resulted, nor was there any primary mortality

Treatment was limited to tumors not more than 3 cm. in diameter involving the trigone of the bladder since the alternative in trigone tumors is total cystectomy with its high primary and secondary mortality. The 3 cm. limit is considered important since greater size of the tumor would necessitate the use of several circular fields with either resultant dosage overlap or failure to include some small ir regular areas in the treatment. For neoplasm of the vault or lateral walls of the bladder the authors prefer local resection if possible. They rationalize the use of this combined surgical and radiation procedure as follows

Cancer of the bladder tends to metastasize rather late in its course and is often fairly radiosensitive and by contact irradiation a large dose can be ad ministered to the tumor base without irreparable miury to the adjacent tissues. It is estimated that with a circular field 3 cm. in diameter and factors the same as specified previously the dose at a depth of I can is only 32 per cent of the surface dose, and at 4

cm only 3 6 per cent.

The authors treated a series of 31 trigone tumors in this manner of which 13 were papillary and 18 infiltrating carcinomas, ranging from grades 1 to 4 with grade 3 predominating. The first 4 cases were subjected to marsupialization and received 10 or 11 treatments each at weekly intervals up to a maximum of about 18 000 r in air in 22 days. The other cases were subjected to cystotomy and of these 15 received about 10 000 r and some of the others less the minimum being 5 148 r which were received in a ample treatment. In addition to the original biopsy, a second biopsy was done in 20 cases at the final treatment and no cancer cells were found in 13 of

survey of the results of this 5 year study showed 10 patients dead of cancer o of them within the

first year of treatment and r after a years. Two others are dead but they presented no evidence of cancer at postmortem examination. Of the 10 survivors 3 have so far lived 5 years another 3 for four years 5 have lived 3 years, and the rest from 1 to 2 Vest

The authors have compared their results with those obtained elsewhere by total cystectomy radon seed implantation, and high voltage external ir radiation and believe them to be at least as good as those obtained so far by these other methods. Fur ther in view of the low primary and secondary mortality in their series they consider the method of contact irradiation preferable to total cystectomy for trigone tumors. LILIAN DONALDSON M D

Borak, J. and Taylor H. K.: Beneficial Effects of Roentgen Therapy in Advanced Cases of Rheu matold Arthritis; Preliminary Report. Ra diology 1945 45 377

A number of investigators have reported favorable results from roentgen therapy of various forms of arthritis such as gonorrheal arthritis tuberculosis gout osteoarthritis and hypertrophic spondylar thritis. However in the rheumatoid (atrophic, proliferative) type of arthritis roentgen therapy has been regarded as less satisfactors

The authors have again studied this subject and during the past two years have treated 60 patients with advanced rheumatoid arthritis by means of roentgen rays these patients had failed to respond to the usually accepted methods of gold therapy vaccines physiotherapy, surgery, or any other method. Ten patients, with a total of 85 joints af fected, were selected for a critical study. The cases fected, were selected for a critical study are tabularly arranged attention being given to the following factors age, sex, duration of the ducase in years previous therapy present roentgen therapy (joints involved, stage and dose) and the results obtained.

Rheumstold arthritis is divided-mainly on the been of the degree of impairment of the mobilityinto 3 stages first stage, in which pain and soft tesue swelling restrict the active mobility of the joint al though passively it can be moved through its full range second stage, in which the mobility is re-stricted both actively and pessively to a varying degree and third stage in which there is no motion at all

Roentgenographically, in the first stage the mint space is normal although there may be a swelling of the periarticular tissues and some decalcification of the bones in the second stage there is usually a narrowing of the joint space, and sometimes destruc tion of the subchondral adjacent hone and in the third stage there may be complete ankylosus.

Pathologically in the first stage the cartilage may appear nearly or quite normal and the only visible change may be in the synovial membrane the second stage is characterized by the formation of granulomatous tissue and the third stage is marked by destruction of the cartilages and their replacement

either by fibrotic strands or osteoid tusme until complete ankylosis results.

The roentgen dose is gauged as follows for in flammatory edema, from yo to row in session for chronic inflammation, from see to 300 r in x to 3 sessions for hyperplana, from 800 to x for r in x to 3 sessions for hyperplana, from 800 to x for r in about 3 weeks and for granulomatious tissue, from x root to 1 600 r in about 3 weeks. In the series mentioned the majority of patients received from 800 to 1 600 r. The factors were sook w 0.5 mm of copperplus 10 mm of aluminum, 2 mm. 30 cm. distance, H V L. of 0.9 mm. of aluminum. Each port was treated three times a week, some foints being crossafred through 2 or 3 ports at each session. In multiple joints two joints were treated alternately so that

treatment was given daily

The results were good in most cases. Relief of the
local symptoms alleviation of pain, and even some
increase in mobility were noted.

### CLINICAL ENTITIES—GENERAL PHYSIO-LOGICAL CONDITIONS

Albaugh C. II : Congenital Anomalies following Maternal Rubella. J Am M Asr 1945 129 719

The author reviews the reports of Gregg Reese, Swan and others on the occurrence of congenital defects following maternal rubella and reports an additional o collected and personal cases

Of the o cases studied by the author 7 of the mothers had rubella, 1 morbilli, and 1 was exposed to morbilli. All of these cases occurred within the first 10 weeks of pregnancy and 4 occurred in the first 4 weeks.

Eight of the 9 infants had bilateral congenital catanets and in 7 the pupillary reactions to light were poor Strabusmus was noted in 7 cases and nystagmoid movements in 4. No glaucoma was noted Eight of the infants had congenital heart de fects and 4 of these showed evidence of cyanous Two minants died of cardiac failure. Five of the infants had definite microcephaly and 3 were recorded as uncertain cases. Retarded development was noted in all cases, and 7 were considered feeding problems.

The author concludes that available data would suggest that too per cent of the mothers who con tract tubells in the first two months and approximately so per cent of those who have rubells in the third month will give birth to infants with congenial abnormalities. The most common lesions are congenial cataracts cardiac defects, deaf mutism and microcephaly. Poor development of the infants and feeding problems are common.

ORLAND B SCOTT M D

Walsha, F. M. R.: Aeropareethesia" and So-Called "Neuritis of Women a Hands and Arms Bril II J. 1045, 21 506.

A syndrome found chiefly in women and charac crized by numbress tingling and uselessness of he hands and fingers is described and its etiology and treatment are discussed. It generally is seen in we groups of women (r) middle-aged or elderly romen who especially in wartime have had to carry a unwonted manual effort, and (2) younger women the are burdened by childbirth in addition to actory or house work. Factors common to all cases re fatigue and debility and the heavy use of the ands and arms Symptoms begin gradually, attain attimum severity after some weeks or months, and hereafter fluctuate in severity according to the con lition of the patient and treatment. They consist of eresthesias most severe on arising waning during he day's work but increasing in the evening often o the extent that they awaken the patient during he night. Positioning of the arms may offer tempoary relief These subjective symptoms predomi

nate although certain objective sigms such as chronic fatigue atonic musculature low-set shoulder girdles and a rare obliteration of the radial pulse on traction of the dependent arm suggest the syndrome Rest alone gives permanent relief such measures as vitamin therapy physiotherapy estrogens or thy rold extract are superfluous

The etiology is thought to be mechanical, in the altered tonographical relationship between the shoulder gardle and the normal upper thoracic out let. The lower components of the brachial plexus and on occasion the subclavian artery are com pressed between the first rib and the clavicle which sags under the general atony of the muscles support ing the shoulder girdle. Pressure syndromes associated with a rudimentary seventh cervical rib or an abnormal scalenus anticus muscle should of course be ruled out however these syndromes are usually unflateral and present more evidence of vascular disturbances in the arm than the less severe normal pressure syndrome of the first rib which is here described. No relationship has been found be tween the syndrome and pregnancy per se.

Rest in bed or the simple essistion of manual work produces appreciable relief and final disappearance of the symptoms. Initially a week in bed and a sedentary position during the day with the arms in slings, effectively brings relief to the patients. Abstention from heavy work, with the arms supported in alings for a longer period when possible, together with aboutler massage and general tonic treatment, tends to prevent recurrence. Analysisis may be used as an adjunct.

PHILIP B CHASE, M.D.

Gorcoran, A. C., and Page, I. H. Post Traumatic Renal Injury; Summary of Experimental Observations. Arch. Surg. 1945, 51, 93

The nature and treatment of post traumatic renal injuries were studied experimentally by mean of investigations of the renal function in the following states (1) hemorrhagic shock, (2) tourniquet shock and (3) simulation of the crush syndrome.

Shock due to hemorrhage was produced in dogs by repeated severe bleeding and transfusion. The shock due to prolonged or repeated bleeding is be hered to cause a depression of the renal function by causing a vasconstrictive ischemia which is not released by the transfusion of blood and restoration to normal of the arternal pressure. The persistence of renal ischemia and anoma in experimental shock due to bleeding seems to explain the prolonged depresion of renal function which may follow bleeding in human beings. Therapeutically it is aguificant that renal denervation does not prevent the vascon striction hence, there is no experimental basis for the treatment of posthemorrhagic urnary suppression by spanial anesthesis or parayertebral block. The nature of the abnormality makes the use of vasoconstrictor drugs illogical.

To study the conditions of crush syndrome, the renal function in dogs was observed during the onset of shock resulting from the experimental application of tourniquets partially occluding the arterial in flow Renal vasoconstriction develops more rapidly and more severely during the onset of shock due to skeletal trauma than in shock due to bleeding in which these damage is milder and more diffuse.

The severe renal damage of the crush syndrome seems to depend on the combination of renal damage from trauma and that caused by muscle pigment. Both post traumatic renal ischemia and myorlobinuria were then produced in rata by the application of a tourniquet and the injection of myoglobin. Dogs were not satisfactory for this experiment as trauma severe enough to cause severe renal ischemia was followed by death within 24 hours, whereas minor trauma was followed by recovery Renal damage is apparently produced by a combination of vasoconstrictive ischemia oluguria, and aciduria, with deposition in the kidneys of muscle pigment or myoglobin.

In applying these principles to treatment, the prevention of the deposition of plament is accomplished by reversing the conditions of alleurus and aciduria, which favor it. The treatment of shock by transfusions and pressure bandages inhibits the renal vasoconstriction on which oliguria may de pend A free flow of urine may occur during the re-establishment of blood volume by transfusion. and when this is not achieved or maintained gelatin may be added to an infusion of sodium factate containing calcium lactate, since gelatin is itself mildly diuretic. A small dose of another diuretic such as sodium sulfate may be given. However the dangers and the ineffectiveness of alkalinization by the injection of citrate as the sole means of treat ment are pointed out. LUCIAN J FROMDUTI, M.D.

Abbott, W. E., Pilling, M. A., Griffin G. E. Hirah feld J. W., and Meyer F. L.: Metabolic Alterations following Thermal Burns. Ann. Surg

In recent years there has been some controversy concerning the best means of combatting shock in severely burned patients. Although there are a number of methods which apparently suffice to tide patients over the critical 48 hour period following an injury their influence on the subsequent course of the patients is not well understood.

The authors compared a group of patients who were treated with plasma with another group who received whole blood intravenously and an electrolyte solution orally The changes observed in various blood constituents and in the elimination of water

and salt were recorded.

From the work presented and previous experi mental work the authors draw the conclusion that the giving of whole blood early prevents or alleviates the anemia which occurs so commonly during convalescence from a burn. Previous observations demonstrated the fact that a state of overhydratus may in some instances, contribute to a decrease in the hematocrit, and also in the plasma protein co-

contration.

Patients with a severe or moderate bern account late large amounts of fluid in the tranmaticed are regardless of the type of therapy employed to combin shock, but it has seemed that the edems distribled more rapidly when salt solutions were used than when large amounts of plasma were administrate When plasma is given much additional protes is provided, but there is no evidence to show that the plasma protein in itself is of more than temporary value in these burned petients. In some of the mthors patients who received large amounts of plasma low protein values were encountered, sai in 3 of the severely burned patients these low values persisted until death. There is no reason to sesent that the giving of whole blood would be more lessficial than plasma for the prevention of hypopoteinemia, but the evidence indicates that the giving of plasma does not prevent the decrease in the

plasma protein concentration. It has been generally believed that by increasing the blood osmotic pressure by the addition of please proteins, especially albumin, shock could be pre vented or corrected. In peripheral circulatory collapse resulting from a burn, however the abuse is rapidly lost. Thus, most of the osmotic effect of albumin or of the entire plasma proteins is transmit and when it is lost through the capillary walls in the injured area it must continue to exert an camete pull toward the injured tissues because of the protein which has then accumulated in that region Since much of the administered protein is lost in patients in shock resulting from a burn, it would seem as though the best treatment would be (s) give a substance which exerted an osmotic effect and would not be lost, (b) to render the injured cap-laries less permeable, if this is possible or (c) is increase the tissue tension to a point at which first would no longer tend to leave the capillaries

excessive amounts.

Apparently there is a substance derived least the surface of fresh plasma which has a coating effect and therefore tends to decrease the capillary perme bility Therefore, it would appear as though whole blood or plasma would have some advantage ord a salt solution alone, but since capillary permeability cannot be quickly or completely restored to normal it would seem logical to give an electrolyte solution so that these tension would be increased.

From the results presented by the authors it can be seen that wide differences were found in the hematocrit readings during the period of shock which could not be correlated with the criest and depth of the burn. The hematocrit, therefore, frequently a poor guide to the type and amount of treatment that is necessary especially since it influenced by a pre-existing anemia, and the rate and number of cells destroyed or trapped from the general circulation at and following the time of in jury and because the normal hematocrit varies quite widely

In the treatment for the first 48 hours at seems logical to give approximately 50 c c. of blood to adult patients for every per cent the body surface is barned, or to give blood in amounts equal to from t to s per cent of the patient a body weight in kilograms. In employing the electrolyte solution it seems desirable to give a slightly hypotonic solution (from two-thirds to three-quarters strength) in order to increase the rate of urine excretion and in a mounts equaling from 10 to 15 per cent of the pa tient's body weight during the first two days following the burn. Since there has been little experience with this form of treatment no absolute rules should be employed but the treatment should be modified according to the severity and the degree of the burn and the size and response of the patient When abook is not severe treatment may be given relatively slowly but if the patient shows evidence of penpheral vascular collapse, therapy should be carned out rapidly until the condition has improved and unne is being excreted. It should be remem bered that the larger quantities advocated are comparable to giving amounts of fluid which are roughly equal to an individual a total extracellular fluid volume (plasma and interstitial fluid volume), hence, when such amounts are employed additional liquids and foods should not be given or should be permitted only in small quantities for the first two days, as this would lead to an excessive fluid intake. If it seems desirable, dextrose can be added to the fluid to provide calones or some form of protein could be added to the electrolyte solution severely burned patients it has seemed that high calone and protein intakes are better avoided ini tially The authors usually give from 800 to 1 000 calories in the form of dextrimattose daily for the first several days which supplements the vitamin intake by from two to five times the normal daily requirement.

In most of the patients excessive hemoconcentration was not encountered when whole blood was given provided an adequate amount of salt solution

was employed.

When the hematocrit is definitely elevated (from 55 to 60 or more) the patient s blood pressure is low and little urine is being excreted, the authors see no reason that plasma should not be given instead of whole blood if it seems to be desirable. By the addition of red cells more oxygen might be carried to the tissues and, hence anoxia prevented but it probably is not wise to increase the proportion of cells too much or the beneficial effect will be overcome because of stases and a slowing of the circulation. Therefore if bemoconcentration is not excessive it probably would be preferable to give whole blood intra venously and an electrolyte solution orally but if the hemstoomt rises to 60 or above plasms or a concentrated albumin solution should be temporarily substituted for blood TOSKER K. NARAT M.D.

Rifkin H. and Thompson K. J: Structural Changes in Early Filariasis Arch Path Chic. 1045 40 220.

The present report is based on a study of 30 cases of early filterials. An ecunophilia of from 6 to 11 per cent was found in 60 per cent of the cases. In the majority of the patients painful enlargement of the superficial lymph nodes of the arm or leg was the first physical sign. In 40 per cent of the cases the gentialis and the lower extremity were involved in a brawny edematous lymphangitis or an acute replidlymorphicultist. In 30 per cent both the upper and lower extremities were involved in the disease process.

Biposy of the lymph nodes showed the presence of the filaria (Wucherena bancroft!) in 20 per cent of the slides while in the other 80 per cent the histology was characteristic of filariasis but the organism was not shown.

During the early stage of invasion, the lymph nodes exhibited extensive hyperplasia of the primary and accondary lymph follides and counophilic in filtration. The lymphatic vessels contained a plnk like albuminoid fluid characterized as fluid lakes the entire histological picture was in conformity with that of an acute systemic allergic reaction with manifestations of cosinophilis, edema, and hyper planas. The subscute and chronic phases of the disease were characterized by an epithelioid cell endolymphangitis and perllymphangitis culminating in a typical granulation ussue reaction and finally fibroblastic proliferation.

Elephantiasis occurred only in those cases in which secondary streptococcic invasion took place

BANIAGE G P SHAPROFF M.D.

Roth G M. and Kvale W F: A Tentative Test for Pheochromocytoma. Am. J M Sc 1945 210

Paroxysmal hypertension and associated symptoms characteristic of the clinical syndrome caused by pheochromocytoms have frequently been de acribed but the differentiation from such clinical conditions as coronary occlusion, hyperthyroidism. histamine cephalgia, migraine, menopausal and anxiety states, and persistent hypertension may he difficult. The most confusing cases are those of the hyperreactors and those in which the patients have essential hypertension with extremely labile blood pressure. In the past the diagnosis of suspected pheochromocytoms was confirmed by the attack which characterized this clinical entity. These attacks were precipitated by various means in cluding physical exertion change in position, massame of the abdomen on the side of the tumor im mersion of the extremities in cold water or the administration of insulin or of epinephrine. Since none of these methods of inducing attacks is de pendable the authors believed that a simple proce dure which would induce attacks at will would be of great help in diagnosis. They review the literature dealing with the subject and then give the results

of their own tests in the hunt for a simple proce dure which might be used in diagnosing patients with tumors of this sort. Their results are summarized as follows

An intravenous injection of c.o.s; mgm. or o o; mgm. of histamine base was given to y; persons, who were divided into four groups as follows group 1; normal persons whose ager ranged from 20 to 48 years group 2; persons the cold presor test whose age ranged from 10 to 50 years group 2; patients who had well established hypertension and whose ager anged from 3 to 67 years and group 4, patients suspected of having pheochromocytoms whose ager anged from 30 to 50 years and group 4, patients suspected of having pheochromocytoms whose ager anged from 30 to 50 years.

whose ages ranged from 30 to 50 years. In the first three groups the blood pressure rose to a level somewhat less than the elevation obtained by the cold pressor test. Except for finishing of the face with subsequent headache, which was most intense in the patients with severest hypertension and pronounced tachycardis, no other symptoms were present. The results of the test were regarded as negative. In a instance typical bistamine cephalgas was produced by this amount of histamine best.

When histamine base was given to 3 patients who had pheochromocytoms, the blood pressure rose approximately to 100 mm, more than the elevation obtained by the cold pressor test. This elevation of blood pressure was accompanied by the character little symptoms of a typical spontaneous attack.

Although the number of cases in this series is anall, the intravenous injection of small quantities of histamune base may be considered tentatively as a worthwhile test in distinguishing the syndrome of pheochromocytoms from other clinical conditions.

PAUL MEDICE, M.D.

Duffield T J, and Jacobson, P H.: Cancer Mortality and Marital Status; an Analysis of Deaths Attributed to Cancer among the White Population of New York City during 1929-41 J Nat. Casser Int. 945 6 9

During the years from 1939 to 1941 the recorded number of deaths from cancer in the white popula ton of New York, New York (15 years of age or over) was 34 010. These deaths were distributed by sex as follows single males, 2,93 single females, 2 855 other males, 15,07 other females, 14,459.

Using these figures and data in regard to the marttal status of the population from the 1940 census the authors were able to draw the following conclusions

from the study of various types of cancer

In cancer of the breast the death rate among
aingle women at ages over fifteen years was more
than 1/4 times that of other women. Between the
ages of 15 and 34 years the rate among the married
women was about one third higher than that among
the single women, but at all ages over 14 years the
single women had higher death rates. Between the
ages of 45 and 55 the rate for unmarried women was
70 per cent higher than that for married women

The mortality rate from cancer of the uterus was 15 per cent higher among married women than among single women. Between the ages of 35 and 74 however the rates were apparently equal.

3 In cancer of other female genital organ the death rate was 41 per cent higher in single women than in other women.

4. For all ages over 15 years the death rate five cancer of the gentlourinary organs in rades vaabout equal in the married and unsurrind group. Between the ages of 45 and 54 the mortality rate among single men was 50 per cent higher the among married men, but it was found to be 35 per cent lower between the ages of 65 and 71.

5. At all ages over 15 years the mortality me from cancer of the buccal cavity was 35 per centhigher in single men than in married men. The mortality rate was slx times as great among men as

opposed to women.

6 In cancer of the atomach the mortality air was so per cent higher among married women that among spinaters. The difference among the sale was not considered significant except after the are/ 75 years when the rate for single men appeared to be lower.

7 In cancer of the peritoneum and other portion of the digestive tract there was no significant difference between married and unmarried women. The rate for married males was 11 per cent higher than that for buchelors.

8 There were no agnificant differences between married and unmarried groups in carcinoma of the

respiratory system.

9 In all other types of cancer (analyzed as exgroup) in both males and females the rates wer higher for single persons. ORLAND B. SCOTT, MD

Coller F A., Iob, V., Vaughan, H. H., Kalés, N. B. and Moyer G. A.: Translocation & Fluid Produced by the Intravenous Admiritration of Isotonic Salt Solutions in Mrs. Postoperatively Ass. Surg. 945, 13 66;

During the past decade, Coller and his make orators have repeatedly directed attention to the potential tomaty of as-called "physiological unit solution, especially when large amounts reintered. They have emphasized that these dearier and the collection of the collection of the operative period of the side kurgical patient.

Studies to determine the manner in which he human body harmonic printra-const infusion of human body harmonic larger intra-const infusion of satisfactions of the satisfaction of the sati

The patients who served as subjects were selected only in that it was determined that they were free of gross cardiovascular and kidney disease.

The normal kidney is able to concentrate charke taken orally at the rate of from 0, e9 to 0,33 mEq per

milliliter. In spite of heavy salt loads no patient studied by the authors approximated this value. As a result of the increasing sait load and increasing hypertonicity of the extracellular compartment, osmotic relationships can be maintained only by a shift of water from the intracellular to the extracellular space Loads of salt created by the isotonic solutions require a transfer of approximately a liters of intracellular water within 30 hours after operation. The edems, a symptom of postoperative salt intolerance may result not so much from the retention of water with sait as from the shifting of water from the in tracellular to the extracellular space. It is unknown how much dehydration the cells can undergo before function breaks down and ceases. The brain cells are especially sensitive to change and the disorien tation so often seen in cases of sait intolerance may

be a symptom of this fluid shift.

The authors summarise their findings by stating that the injection of isotome sodium chloride solutions was attended by an average retention of 35 per cent of the chloride and 19 per cent of the chloride and 19 per cent of the chloride and 19 per cent of the water 30 hours after the operation. Such retentions of salt indicate a withdrawal of approximately a liters of fluid from the intracellular compariment in order to maintain isotomicity. The indusion of hypotomic solutions resulted in the average retention of 27 per cent of the sodium 32 per cent of the chloride and 30 per cent of the water during the same postoperative period. Extra water is thereby provided for excretory function of the skin and lungs and the intracellular compariment is

The human kidney under the conditions of the experiments, did not elect to guard a physiological saline solution

The authors conclude from their experiments that if intravenous infusion is indicated in the postopers tire care of the surgical patient, hypotonic solutions (0.45 per cent sodium chloride or better 0.38 per cent sodium chloride plus 0.11 per cent sodium thoride plus 0.11 per cent sodium be carbonate) should replace the isotonic solutions commonly in use. JORKER K. NALT M.D.

### GENERAL BACTERIAL, PROTOZOAN AND PARASITIC INVECTIONS

Rubenstein A. D., Tabershaw I R. and Daniels, Jt Pseudo Gas Gangrene of the Hand J Am If Arr 1945 129 659

Three cases of a new syndrome characterised by the rapid appearance of subculaneous gas tumor masses within a few minutes after a superficial accration of the hand occurred in a plants, where an alloy composed of 90 per cent magnesium was being used. Each patient had handled this material in a finely powdered form prior to the occurrence of the fajury. It is possible therefore that an ethological relationship exists between the alloy and the syndrome.

Because this syndrome may simulate gas gan grene, it is important that its clinical characteristics be borne in mind in order that unnecessary surgical procedures may be avoided. The syndrome is characterized by a rapidly developing swelling of a superficially injured part with crepitation and with an almost insignificant constitutional reaction.

SAMUEL KAHN M D

Anderson D G and Jewell, M: The Absorption Excretion and Toxicity of Streptomycin in Man. N England J M., 1945 233 485

After oral administration, streptomycin is not absorbed in amounts sufficient to produce detectable concentrations of the drug in the serum. The failure of the drug to be absorbed from the gastrointestinal tract is not due to the mactivation of the streptomycin by the gastric luice.

After intramuscular or intravenous injection of a given amount of streptomycin, the curves of the serum concentration of the drug do not differ significantly except during the first few minutes after injection. Following the intramuscular or intravenous administration of a single dose of streptomycin, from 46 to 87 per cent of the dose injected can be recovered in the urine within 24 hours.

Streptomycin is excreted more slowly by the kidneys than is pencillin. It appears likely that effective blood levels of streptomycin can be main tained by administering the drug at intervals of from 6 to 8 hours.

The intrathecal administration of streptomychi in doses up to 20 000 units does not produce signs of meningeal irritation. With doses of from 12,000 to 20,000 units an appreciable concentration of the drug can be maintained in the cerebrospinal fluid for at least 24 hours.

No serious toxic reactions follow the injection of aingle doses of streptomycin in amounts up to foco, oo units or after the continued administration of the drug for periods of from z to 3 weeks, in dozes totaling from z 725 coo to 18 130 coo units. The intravenous and subcutaneous injections of concentrated solutions of the present preparations of streptomycin cause too much discomfort to warrant the use of these methods of administration. The drug can however be administered in an intravenous influsion without the production of un pleasant symptoms. Intramuscular injections are fairly well tolerated for periods of from one to two weeks. Therapy continued beyond this time may cause severa discomfort.

Three cases of infection due to a gram negative bacillus, and treated with streptomyon are reported. No conclusions concerning the efficacy of

streptomycin can be drawn from them.

much as four million units per day. The streptomy cin unit was that quantity of dry material which inhibited the growth of a strain of escherichia coil in r.c., of nutrient broth or again.

In a patient receiving two million units of streptomycin daily, the blood was found to contain 31 units per cubic centimeter of the antibiotic. The intravenous administration of streptomycin was not attended by severe thrombosus of subcutaneous imitation when infiltrated Intermittent intra venous administration resulted in a high concentra tion of streptomycin which then fell rapidly. Intermittent intramuscular injection appeared to be the method of choice because effective concentrations were present in the blood for from a to 6 hours high potency such as 100 000 units can be given readily in r c.c. of normal saline solution Subcutaneous administration of streptomycin also maintained effective concentrations in the blood Intrathecally single injections of 100 000 units were given for meningitis without any serious reactions and with significant concentrations of the antiblotic for as long as 24 hours. The nebulgation of streptomycin for tracheobronchial pathology for a period of 4 weeks at 400 000 units per day caused no serious reactions The oral administration of streptomycin at 125 000 units every 6 hours caused a significant reduction in escherichia coli in the bac terial intestinal flora and was not followed by any absorption into the blood stream. Diffusion of streptomycin into the cerebrospinal fluid did not take place except when large doses were given parentally during meningitis Placental transmussion of streptomycin from the maternal blood stream to the fetus occurred readily after parenteral administration. Streptomycin was twice as con centrated in the biliary system as its average con centration in the blood Liver function was not impaired by this antibiotic as evidenced by the normal values of bile and bile salts. From one half to three fourths of the streptomycin was excreted in the urme in 24 hours.

Toxic reactions to streptomycan were rare but may be manifested by chills and fever generalized flush ing toxic crythema urticaria, and joint pains Streptomycin did not appear to have any effect on the hemolytopletic system. As a rule streptomycan did not impair real function except when extremely large amounts were given, as a result of which there was evidence of temporary renal irritation.

#### DUCTLESS GLANDS

Gabrilovs, J. L., Kert, M. J., and Sofier L. J. The Use of Thioursell in the Trestment of Patients with Hyperthyroidism. Ann Int. M. 1945 25 537

Thoursell was used in the treatment of 54 patients of whom 51 had hyperthyroidsm and 5 had sontoxic goiter Thirty three of the patients were reated successfully with thoursell for varying

periods of time the longest period of continuous therapy being to months. Four of the patients had recurrent hyperthyroldism, and the remainder had diffuse hyperplasia or toxic nodular gotter

Three patients with hyperthyroldism were successfully prepared for operation with thiouracil, but 4 patients with hyperthyroidism failed to respond satisfactorily to thiouracil. The latter were subsequently prepared with iodine and successfully operated on. In 11 instances thiouracil therapy was discontinued because of severe tonc reactions.

The following toxic reactions were encountered conjunctivitis in 5 cases edema in 1 case drug fever in 4 cases leucopenia in 1 case and agranulocytosis in 6 cases. Some sort of toxic reaction was found in 31 per cent. The development of agranulocytosis or drug fever are indications for the cessation of thera py Treatment may be safely continued in the presence of conjunctivitis.

Studies of liver and kidney function throughout the course of treatment failed to demonstrate any ordence of injury to these organs resulting from the thiouracil However instances of toxic hepatitis occurring during thiouracil therapy have been reported

Because of the frequency and severity of the toxic reactions thiouracil should be used under the follow ing circumstances: (i) in the preparation of lodine fast petients for operation (2) in older individuals with hyperthyroidism, in whom operation is danger out and (5) in patients with recurrent hyperthy roidism who have been operated on twice or more Savez, Kams M.D.

#### SURGICAL PATHOLOGY AND DIAGNOSIS

Stewart F W Foote, F W and Becker W F Mucoepidermoid Tumors of the Salivary Glands. Ann Surg 1945 122 820

The authors for many years have been interested in a group of salivary gland tumors different structurally from the commonly recognized tumors of this type They were unable to find adequate clinical and pathological descriptions of these tumors and were in doubt as to their terminology histogenesis and prognosis Gradually by correlating the histological structure and clinical course it was nosaible to distinguish two structural types one capable of localized growth and the other of metastasizing The term "mucoepidermoid salavary gland tumor expresses two of the principle histological features. The authors believe these tumors represent a little more than 5 per cent of all combined major and minor salivary gland tumors and they deserve more prominence than they now possess.

As a group these tumors show a broad range of histological variation depending on the relative proportions of different cell elements which are present and tendencies to ward diffuse overgrowth by a single cell type. There is no gross uniformity some are cystic, some solid, some encapsulated, others not. Recurrences may be situaturally different

from the primary growth. It is likely that many of these tumors have been classified as cystadenomas basalomas evlindroma adenocarcinomas or socalled mixed tumors.

The authors then h t a number of cases in the literature which may be tumors of thi clas ification. They believe that thi group has been dealt with sparingly in the literature and is a group which is unfamiliar to many experienced pathologists

The material f r this analysis was obtained from the records of the Memorial Hospital, New York New York pertaining to approximately 700 major and minor salivary gland tumors of all types observed between 1928 and 1913. Of this sence 45 cases were clas ibed as mucocolilermoid tumors All of these contained mucous cell and cells with epidermold qualities.

All evidence in this material points to the salivars gland ducts as the anat mic site of origin of mucoepidermoid tumors. These tumors can be separated into two histological types—benign and malignant The term benign as used here does not necessarily imply innocent behavior but does mean that thus far the authors have not observed meta tases from these tumors. Malignant means a hist logical structure a sociated with the ability to preduce

regional node an I distant metastases

In 14 f the 26 benign tumors the predominant cells were epidermost in a they were mucous and in a they were basal. At lea t three cell types w re represented in the majority and the presence if multiple cell types in large numbers was more character ratic of benign than I malignant tumors. In a restricted area, the patt in depends on the predominant cell type. If basal or intermediate cells prelominate a unil rm mosaic result with sheetlike groups of varying sizes, the peripheral margins of which are sharply delineated as seen in a basal cell enthelioms or a sweat gland adenoma

In areas of mucous cells ne sees instead quite small or even greatly dilated ductlike structures which are lined by one or several cell layers. Some of these areas assume papillary qualities and not in frequently possess a central core of vascularized fibrous tissue. In some of the ductlike or cyrtic areas are found "mucus pool which stain brilliant red with Mayer's mucicarmine. If there is over production of mucus, dilatation ensues with erosion of the lining epithelia disruption of the basement membrane and leakage into the adjacent tissue This may result in necrosis or a marked secondary inflammatory process with an associated foreign body reaction with multinucleated giant cells.

In foci of epidermold cells, it is unusual to find complete di sociation from basal or intermediate cells, and when the cells assume squamous qualities there is apt to be a diffuse unicellular overgrowth These cells are similar in size and shape their staining qualities are uniform and mitoses are few One is ant to regard the tumor as malignant until greater familiarity with its structure is obtained About one third of the benish tumors showed certain

areas composed of cells hydropic and smiles of similar to the clear cells of a renal adenocaronors One may assume that these cells contain much be none takes the mucicarmine stain.

In 14 of the 10 malignant tamors, epidentsal cells were predominant and in only \$ were work cells even second most frequent. By epilemod cells is meant cells similar to basal cell caremona esquamous cells without intercellular bridges and Leratohyalme granules Intermediate cells, slighty larger than a basal cell and with more rescuir nuclei and more abundant cytoplasm, were a be quent cellular component of these malignant tumor. Columnar cell were rare True squamous cells shi intercellular bridges and keratohyaline granin were found in c cases.

The outstanding characteristic of these malicum tumors is a diffuse proliferation of rather real. moderately hyperchromatic rounded and oral acin sheetlike arrangement with a tendency towns palisarling at the outer layer surrounding the reliferating sheets and pegs of the tumor. The =pression is one of a basal cell coitbelions with sive thing added, and there is an appreciable resemblant t the transitional cell careinomas of other locativa.

Malignant tumors show little tendency to larg microcysts. Tubular and papillary features are refrequent and mucus pools practically sent ead. The histological structure of meta tases sharply a-

flect the variable structure of the primary keet Mucus cells were found in metastases in 5 cases The 14 primary and 9 recurrent benish tumor

varied in size from 4 mm. to 4 cm. in dancies averaging between a and 3 cm. They were ovel b shape and well circumscribed, usually with a per capsule. Usually these tumors were moderately fra but not indurated A majority were at least party cyetic and contained nearly clear opalescrat, blood stained mucoid material usually visid. The nearly solid tumors were gravish white or grayatpink but not lobulated. About one-half of the tumors showed discoloration due to secondary hemorrhage and/or pecrosis

Of the 19 malignant tumors only to were exist (s primary and 6 recurrent) The majority were be tween 2 and 3 cm. in size and the largest 5 cm. Let of encapsulation was a distinct feature and mot of them were obviously infiltrative There was med less eyet formation than in the benign tumors, and none showed grossly vuible mucus aggregates. The were distinctly firm cellular, oraque grayib akm. and homogeneous with fairly common hemorism and necrosis.

A study of the ages of the patients at the oriet of their symptoms shows a general trend for the benig tumors to occur in a younger age group. Forty-tro per cent of the benign tumors occurred to patient more than 40 years of age and 65 per cent of the malignant tumors occurred after this age one of the benign tumors occurred after 60 years of age. but one fourth of the malignant tumors and got

symptoms after this age

abdomen.

The parotid salivary glands were the most com mon sites of both benign and malignant mucoepi dermold tumors the majority being benign other major salivary glands were involved only ex ceptionally. Nearly one third of the tumors (mostly malignant) occurred in the minor salivary glands in a variety of locations.

Painless swelling was the outstanding symptom in the benign series. Slow growth and absence of in volvement of the facial nerve were commonly re ported Several patients had local pain or bloody sputum and a cases were found on routine physical examinations. There was a wide fluctuation in the duration of symptoms. Nine patients had symptoms for a year or more and several had had them for five vears.

The syndrome was far more varied for the 10 mahenant tumors. This was largely due to their location within the oral and nasal cavities and the more aggressive growth of these tumors patients (42%) reported a painless swelling as the original symptom. Three noted painful swelling Others complained of nosebleed a mass, lacrimation or a nasal discharge. One patient first noted a metastatic lump in his neck. Other symptoms which occurred during some phase of the disease were numbness of one side of the tongue, interference with speech, dryness of the mouth and sore throat. Lacrimation, trismus and facial nerve weakness were seen in r case. Pain was a prominent symptom in most cases sooner or later. Three of these cases gave a history of cachexia and weight loss. About one half of the patients reported a rapid increase in size of the mass.

Six of 10 patients had symptoms for less than one year Two cases are presented as evidence of the transformation of benign into malignant tumors

The benign tumors whether recurrent or not, were nearly all described as firm. An occasional one was elastic or rubbery and only 2 were considered cystic. Most of the tumors were well defined but not as sharply as the so-called mixed tumors. Five of the so paroted tumors were firmly fixed and several others had infiltrated the skin. All of the primary tumors were single but 2 of the recurrent cases showed multiple discrete nodules. The 5 benign tumors of the minor salivary glands were submucosal except for 1 polypoid nasal tumor. Two of these tumors had ulcerated through the mucosa.

The malignant tumors whether primary or recur rent were firm fixed, poorly circumscribed and in filtrative Both submaxillary tumors fungated through the skin. One parotid tumor interfered with the facual nerve All but 2 of the minor salivary gland tumors showed mucosal ulceration. The intra oral and intranssal tumors were complicated by erozion and penetration of adjacent bony structures

In 11 of the 26 benign cases the tumors had recurred after surgery when first seen by the authors (3 of the 11 were twice recurrent) Late recurrence may be characteristic of these tumors. Ten of the recurrent tumors were paroted and I nasal

Of the 10 malignant cases o were recurrent after surgery when first seen, (5 of the 9 patients had more than 1 re-excision) Rapid recurrence was much more likely in this group. Ten patients on initial examination showed clinical evidence of metastases to the cervical or supraclavicular lymph nodes. In 4 of the 10 cases the primary tumor was in the major salivary glands.

Distant metastases were seen in the cervical mediastinal para-aortic, and iliac lymph nodes in the lungs pleurae myocardium and liver and in the subcutaneous regions of the face scalp axilla and

In 14 of the cases of benign tumor treatment was

started more than 5 years ago. Three have been lost to follow up and were free of disease 1 2 and 2 % years respectively when lost. Nine patients were alive and free of disease, and a had recurrences which are probably inoperable. Two of the 5 year cures were from irradiation alone and 3 followed surgical excision alone Four of the o cases were subjected to combined surgical excusion and radia tion treatment. Radon seeds were implanted in the operative area in each case. One case received additional external irradiation also

The highly fatal character of the malignant group is shown by the fact that 7 patients are dead surviv ing 2 t x 8 and 0 months and 2 and 10 years after treatment respectively. Five of these 7 patients had clinical or nathological evidence of metastases when treatment was begun. Twelve patients are living 2 have locally uncontrolled tumors and 1 has subcutaneous metastases. One patient alone is alive and free of tumor after 5 years. Two are living 3 1/2 and 2 years respectively and believed to be free of tumor The follow up period in the remaining 8 still living is too short for significant comment.

#### HITS STRIKES AND OUTS IN THE USE OF PEDICLE FLAPS FOR NASAL RESTORATION OR CORRECTION

VILRAY P BLAIR, M D FA.C.S and LOUIS T BYARS M D F.A C S St. Louis, Missouri

THE purpose of this paper is to illustrate some of the underlying factors that can make either for success or for failure in the substitution of skin bearing flans for lost or lacking nasal tissue Such flaps may be used alone or supplemented with cartilage implants or free skin grafts. The need for nasal restorations or corrections might come from (1) congenital absence (total or partial) (2) postnatal growth irregularities (3) tissue loss through disease accident or surgical destruction

#### PREOPERATIVE CONSIDERATIONS

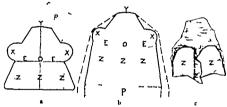

The quality of final outcome and number of operative steps required may be more closely related to the thoroughness of preoperative study and planning than to the skill expended In complex cases it is worth while to check repeatedly the tentative plan otherwise some oversight might necessitate a midstream mod ification causing delay increased operative steps and ultimate disappointment Disappointment is not helped by the feeling that more persistent preoperative study might have prevented the debacle

This survey should compass not only the tissues of the external nose proper and the sources and kind of repair material available but also the condition of the foundation tissues (Figs 7 11 18 26) and of the nasal passages (Figs 5 8 9 15) The latter is unfortunately often missed Fitness and fit are as essential here as in the foundation of a house. The proper time for securing these is before and not after the nose or the house is added Therefore before considering the external nasal repair the underpinnings breathing space and the usable nasal remnants should receive careful scrutiny. Loss or displace ment in the nasal framework or of the related cheek hip columella or septum should also be determined (Figs 5 and 16 ) When present correction of such loss or displacement should be at least visualized before the nasal repair is planned. Restoration of the foundation and repositioning of tissues to give breathing space are parts of one problem selection pattern ing and transplantation of repair material are parts of another problem These two must at least be correlated mentally before surgery is undertaken

Recorded sculptors of less skill than Phidias all preferred to materialize their ideas in clay before risking a false cut on a marble block

Presented before the American Association of Plastic and Reconstructive Surgery October 7 043. Bernard G. Sarnat, M.D. assisted in assembling the material for the case histories

For cancerdings and emphasis the greatly reduced prints in the figures have been preopriately blanked and pendled but without intentional secritics of lines of verity. This study is based on selections from considerably more than knowled fap restorations.

Lie a. Diagram of a forehead flan Z Z' Z is for estibular lini g and columella. Lateral dashed lines (Z, Z) on the lower part show the minimum with of forehead flap for extilusiar folding. Dark outline hows desirable with, often allable in men with receding hairbnes. Making dorsal covering and weilfula infoldings in adequate airway from forthead flap less than 5 centilmeters wide can be difficult.

b. Tharram and plan for infracts icular flan, bether arm or body pulicable here unserent bem or cart lage remains to ri form to the new pose (fig. 18) Observation of eraft lined flaps suggest that 1th no supporting framework a soluble for a near fap, patterned ther the outer dashed line of b the covering part, presi-ously thinned and lined ith contracts a right kin graft should failly ell hold its 

hours I' the messal abstract from which the columella was mad

SERIES A GROWTH OR NAMED THE APPLANTED FLAPS. I this series of cases, teen age or younger some useful comparisons can be mad of growth changes in early repair Discreations the disparity of ages, an ant communion cabe made let cen the case in Figure 2 and that in Figure 4 Though the losses ere simils the former as repaired

with a forebead flan and the latter with an arm flan. The relation of size to growth of a pose made forebead flap will remain more stable and ith an arm or subcla icula flap. If he rather stable if the major part of the supporting structures ha need ted I tact I have a present case in which the estimated allowance for growth proved insufficient.

I grow ng none with est balar haing and covering derived from foldings of the same flap, the similar growth impulse may in time cause ertical making of the confined liaing layer as can be seen by company the /in Figure 3 where repair was made from a arm flap. This was less evident of the forehead flap repair in Figure 3, as shown by the photographs taken a years after final oper ation in each case

In Figure 5 remained ith forehead flan, done the much later are the disproportional changes with growth are less evident. At no stage was there wrinking of the vestibular lining. I igure 5 shows also that even in the use of forthead flap, it is necessary t mak allow nee for some skrinkage emphasized by the change in shape of the ala and tip in a weeks time (compare g with h)

Regarding the cases in Figures 6, 7 and 3 sh enital infection, the common characteristics de elopment of the supp suces with activ or niceration in the line lon of the no. or cartilard. in Figure 6, as made

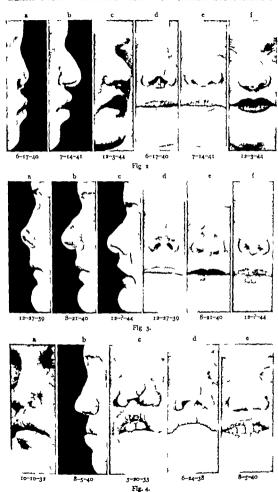

but llowance as mad for growth and rossible later carelare implantation. This accounts for the marked dotal con exity of the completed nose I Figure 7 the child originally had almost no supporting framework, heliqueven columella and premanila. The foldings for alse and columnella here shoung ere readjusted shortly afterward to gi better breathing space, c and h Photographs sent t us approximately 4 years after app cation and adjustment of the flan. Comparing how that the right als berder has become lower than the left, but this could, even now be readjusted. Seven aperative steps, major or misor ere required over period of

j)can. 1 gl l, 5 years old, ball received destructor and d, there condition its wide radiation in infancy scarring of the lower third of the nove and related columns b and Condition 4 months after surfacing the sore and restoring the estibule ith a upper arm dap c and i Photographs taken proximat by 4 years after find at

partments. It! deficult tithis time t determine bether all of the shortening show in f is real or partially due to some aptilti g in the pose of the photograph that as sent to on live operative steps, major or misor ere dose la les

is t years. Hig 4. Thi supersensitive child was 8 years old her war was intilated. Early arm flap repair failed t heep on third page following)

pace with namel growth. a, Shows radium destruction in infancy causing scarring and crumpled ala. c, After excision of damaged tissue, sufficiently extended to insure drenlation in the transplant, an oversize flap was implanted in the belief that it would provide for future growth d, The years later the above allowance for growth had proved insufficient. At this time the original flap was removed and the distortion was released. An abdominal flap was jumped via the left hand and adjusted. b and e Photographs taken 2 years after final repair. Twelve operative steps, major or minor were done over a period of 8 years.

The new nose is not central in its relation to the lip or the teeth.

Fig 5 A girl 17 years old, was injured 9 years previously a, c and? Photographs show adjacent partial nose and cheek loss with incidental alar distortion and vestibular block. The skin graft on the upper lip had been applied shortly after injury d and g Taken r year after covering the right half of the dorsum with a forehead flap infolded to line the vestibule and piece out the ala. The intentional exaggeration of the alar circumference of the vestibule still shows. Gravity was expected eventually to correct the draw-up of the new alar border b e and h, Show final adjustment of check scar, alar attachment, and symmetrical shrinkage of the alar circumference but the alar border is still above the level of its fellow

This required eight operative steps, major or minor over a period of 1 year

The alar draw up cited persisted.

Fig 6. Congenital deformity in a girl 10 years old a and b, Condition at first examination. After release of the uptilt, repair was usede with a right forebead flap, with a pedicle at the left brow wide enough to supplement both ining and covering, shown in c. d. The covering part of the flap is in position with a prolongation between the reparated also to piece out the tip, e and f Last observed result, 21/4 years later This was done in six operative

steps, completed in 3 months.

Subsequent growth will likely modify the convexity of

the dornal line.

Fig. 7 Congenital deformity in a girl, aged 12 years. and c, Show the condition with the lip repaired and a cartilage previously inserted in the upper two-thirds of the domain. b d and e, A flap from the right lower abdominal Quadrant was jumped via left wrist to the dorsum after removal of the nasal covering and the lower part of the original cartilage implant. Later the columella came from an inner lateral palm flap implanted first into the pasal tip and subsequently into the up, b and e. Owing to circum. stantial delays, the 8 major and minor operative steps

were spread over a period of 4 years. Fig 8. A girl aged 17 years, with history of premature birth reported weight 11/4 pounds. Congenital infection with early ulceration of lips and nasal lining. Left vestibule almost obliterated columella retracted and much of lower lip missing a and b. b, The two vertical lines between s and t indicate full thickness incluious which, after discarding the scarred lining and the related cartilagmous septum, per mitted the turning in of the skin to furnish attachment to the future lining flaps, s' t' o in c X and W indicate full thickness flaps (8, b) In c, flaps Y and W have been rotated to give vertical length to the lip F and Z indicate primary raising of the nasal flaps. d, The nasal flaps Y and Z were again raised, the distal two-thirds of each thinned doubled back and fixed with sutures to heal, raw to raw to help piece out the vestibular hning

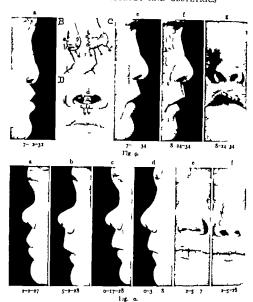

The nose as shown in e and f was accomplished by turn ing in : f' as partial lining, attaching the masal flaps I and Z sutured in the midline. The columella came from some extra width on the mestal border of Z, originally provided for that purpose. We have several times used this double flap where the forehead was wide but too low to furnish it in one piece (Fig. 32). The dorsal line of junction can, with careful cutting and suturing be made all but invisible. Where a nose is patched with an arm flap, the line is ant to be evident, less so if enough material was provided to allow a secondary adjustment.

e and f Show the final result. At recent steps a crescent piece was sawed from the mandible to shorten the vertical chin-lip length. Later the two halves of the lip were sepa rated. A folded arm flap was implanted into the midpart to give more than double the transverse width of the previously tight lower lip. At the time of transfer the rolled edge was left overfull to permit later an attempted reproduction of the natural slight ridge of the mucocutaneous function

This was accomplished in 8 major or minor steps done

in 514 years time.

A wider insert would have avoided the slight "V" at the right border

SERIES B DEFORMITIES INCIDENTAL TO A SHORT HASAL TUBE

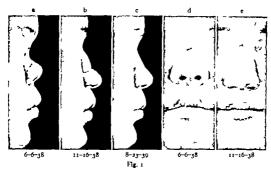

These deformities might be congenital, as in Figure 9, or due to infection, as in Figure 9, or acquired in growth, as in Figure 2. In some, correction might necessitat synchronous lengthening of the massi covering (Fig. 11)

Fig. 9. a, Cirl, aged 1: years, with columella and vestbular floor short, but with full vertical length of the doorsom. Correction required several very distinct steps. The first was accomplished by dividing the short columella from the lip and septum. This mubble of columella was fixed in a salvanced position, shown in b. In b, a roughly indicates

ining basis on the turn waved the flow of the restribute and attended will forward in such lateral wall. I be indicate the lower border of the als, of the original position of the columella. c. Wide undertuding permitted the border and lower part of the alsa covering to be moved downward and forward, with the resulting lateral defect in the bling, indicated by s'= a while the litherated stromp of columella was moved forward to s'. d. The haing defect as filled in with the ra lash of a sessilior stated lateral pathor flap, introduced through the noarth. After circulation was established, the prickles f.f. or drivided in the midfles of the four The columbia was later pieced out from the remaining palsar people. e. show the result of these implantations believe to the result of these implantations have not say between the register of these implantations have not expect brought the none or lay sufficient for the report of the register. The correct this, the ere columbias part freed from the septem, the columbia is the result of the septem. The columbia is the result of the septem of

This was done in seven operative steps, which for extrinsic reasons were extended over a years.

Fig. 10. A woman, so years old, had a flat bridge size childhood with history of ulcerations and repeated treat-

sents. a and c, Show addle nose and loss of vestibules fining, but downs! covering and columnlis of sufficient length abort nasal tube. Disregarding the presence of the columnits which was lacking in Flyure o, the plan of length ening of the vestibular floor and walls is identical with the exception that in Flyure o, d, the swallow tailed flap was introduced through the common nostril space while in this case if, was introduced sublability.

b. Shows the immediate result of the tubal lengthening shich for lack of cartilage support was but partially main tailord in the healing process (see c) but a secondary under making of the dorsum and the implantation of cartilage gave the result shown in d and f. The above procedures give about the limit of lengthening solely by additions to the liming. This was accomplained in 7 operative steps, major or minor, over a period of 15 months.

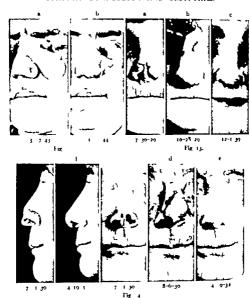

Fig. 11 Faulty postnatal development with shortening of both the donal line and the nassl tube in a man, 21 years old, a and d, Here the approach was through an external incision as indicated by the dashed line in a. The superficial tissues were stripped as far down as the dotted line, at which level the alse cardiages and floor of the vestibule were cut across. The lower part of the septum and the related soft tissues were mobibiled as in Figure 10. In Figure 0 the lining flaps were entered from below met at the dorsum and were wedge shaped. In this case, the lining flaps entered through the dorsum and met at the middline of the floor were cut across at the dorsum square-ended both above and below. The covering flap in b, came from earther up on the pedicke. Later developing sear constitutions were dealt with through the noatrils the need for the latter is less frequent after implantation of a forehead than of an arm flap b, Shows the condition several months later c and c. Views of the final result, show the donal line brought forward, accomplished by surface readplutment and dorsal implantation of costal cardiage. Four years later airways were reported satisfactory. A total of 7 oper after airways were reported satisfactory. A total of 7 oper after airways were reported satisfactory.

Split graft in forehead could be replaced with pigment infected full thickness graft.

#### PLAPS

There are three general sources from which the flap might be taken directly or jumped (1) the hair free regions of the forehead and face (2) the arm hand anterolateral areas of the trunk and the groin (3) pedicle flaps de rived from the nose (Figs 1 27 and 29) Of prime importance in the selection of tissue for a flap is the recognition of variations in the suitability intrinsic to the donor area. The outstanding characteristic of those taken from above the mandible is quality from below the clavicle is quantity. In hair free areas of the neck those factors merge but with qual ity still dominant (Fig 17) A more detailed but terse differentiation of aptitude is given in Table I

Human flap material is precious The surgeon will best serve the patient and himself by first making patterns from plaster-clay restorations of what he is attempting to re-establish (5 a) One that does not exaggerate the surgical possibilities serves as a usable working pattern helps the patient to visualize better the aimed at result, and gives some idea of the intricacies involved Even then it is hard to gauge the patient s buoyed up expectations. It is good practice to hazard the remark that the oper ative result will most likely fall quite a bit short of the model—unfortunately often true In faces both operated upon and not the natural color and mobile expression will ca mouflage moderate defects in contour which on the white cast stand out glaringly (9)

lig 14. a ndc Loss of tip of note from according to man 33 years old. A frinquier flap a few me to the left check ith the base: I the bridge of the new set of the bridge of the section o

There is room for judgment in each case but the secret bere hardly warrants repetition of the two-step operation.

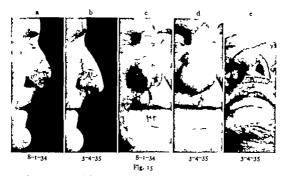

Fig 15 a and c, One year after loss of tip and columella narrowing of the vestibular floor and inspiratory collapse with airways obstructed in a man, 40 years old The repair was made in the standard way from a forchead flap but it lacked intrastitial support. b, The inhabitor collapse was controlled by undermining through incisions just within each vestibule, permutting insertion of thin strips of costal actillage with perichondrium, facing metally to cause a

slight outward bulge. Through incision made at each labial alar junction and undermining, a narrow stiff strip of cartilage was inserted which restored the width of the vestibular floor d and e

The result was attained in an major and minor steps in 6 months. We have through the same approach put in a single piece of booped cartilage, or a single piece for each side can be inserted through a short dorsal skin incision

Supraclaricular flaps To have the completely made nose of acceptably small size especially upon a woman the part of the flap that will form the alae and tip and be infolded for lining must be made very thin and at least 5 centimeters wide (Figs 16 and 26). This is often not possible on a woman's fore bead unless some scalp be included or taken as a bilateral double flap as in Figures 8 and 32. In older men however a receded hairline may become a blessing (Fig 15) (5 a 8 a)

Face forehead and small neck flaps can ordinarily be safely transferred after two pre-liminary steps (Fig 12 was an exception) (1) Make circumferential or both lateral in cisions leaving but a small artery-carrying distal pedicle undermine completely but avoid stripping the periosteum (2) After 10 days or longer but only after determining total absence of edema and the efficiency of the proximal blood supply by finger pressure on the distal pedicle divide the latter and suture (Fig 13)

With a well prepared forehead flap it might be possible and expeditious to thin infold and completely attach the whole nose at one sit ting However caution may dictate final thinning of the dorsal part only and temporary adjustment of the infolded part at the time the flap is first brought down. To insure a free vestibular airway without grossly in creasing contour secondary drastic thinning of the infolded part will ordinarily be required. The one step thinning and affixing operation is most suitable in making a large nose of an older man where the blood supply is usually generous. For small noses the two-step application is almost mandatory

A forehead flap with a temporal pedicle is poorly adapted to make a complete nose but can be used for dorsal covering lining (Fig. 6)

or patching the cheek (Fig 23)

Infractarcular flaps Arm or body flaps should be raised in at least three stages spaced at proper intervals (1) Make but one lateral incision at a time preferably full length down to the muscular fascia and undermine in that plane more than one half way across the proposed width (2) 10 days to 3 weeks later make the second lateral incision and complete the undermining (3) after a similar interval or longer cut half way or completely across

the distal pedicle and if circulation warrants the nasal covering part of the flap might be thinned and put up at this time. Never cut across the distal end until the flap has ac quired an adequate circulation as proved by pressure test. Venous engorgement can cause gangrene in a pendant flap in spite of a gener ous blood supply

At some step the pedicle of a long arm or body flap might be partly or wholly tubed or the raw surface of both pedicle and bed can be covered with split skin grafts at this time except the area to which the excess of pedicle will ultimately be returned. It is desirable in the original planning of a flap to allow for proximal lengthening should a par tial loss occur at the distal end (Figs. 30 and 31)

For disproportionately long and narrow flaps on the trunk or neck sectional tubing interrupted by temporarily retained attach ments to insure immediate blood supply is a practical plan These supply bases are later detached and tubed consecutively

With a forehead flap where the pedicle comes from above a few tacking sutures are sufficient to hold the transplant in place but to compensate for the pedicle drag of a flap brought up from below we use one row of buried very fine white silk sutures on either side so placed as to give some up-crowding when tied with a superficial row of fine sutures to insure accuracy of skin approximation With a forehead flap the buried sutures might be omitted. In either case, the superficial sutures are of black silk the knots are not drawn sufficiently tight to leave marks and might be removed in 3 days. These are re placed by a one-layer patch of gauze affixed with flexible collodion. A heavy skin suture deeply placed at the lower end of the alar bulge may be used both to fix and shorten the vertical base of the bulge which will tend ultimately to give a more natural lateral full ness to the ala.

The weight strain is further eased by a gauze strip fixed to the skin with fresh flexible collodion lengthwise to the pedicle below and above to the forehead. If into this traction line a section of elastic rubber band is introduced the lift will be more uniform

#### DIFFERENTIAL CHARACTERISTICS OF SUPRACLAVICULAR AND INFRACLAVICULAR

FLAPS TABLE I -

Flaps taken from face or neck

InaN I Hair free donor areas may be embarrassingly limited especially on the forehead of a woman or

the neck of a man a The scar of the donor area is always in sight, though this can be more or less camouflaged by skin graft and intrader mal injection of color Try to avoid a forebead defect on a woman.

Flaps taken from trunk or limbs

AHCan be made almost any size

A. Body hair may be entirely negligible Most donor sites are

hidden by the clothing 3 Certain of the objec tionable factors cited below in the inant group do not hold true for flaps taken from the front of the wrist or bor der of the palm Both are hairless and the lat ter is of good consistency and color and does not shrink. These latter can be particularly appropriate for certain small repairs such as restora tion of a columella or

The forehead flap is intrinncally the more de strable. It is relatively firm in substance with just sufficient elasticity to retain some spring making it self-support ing When lolded to a sharply molded form it will shrink very little in healing or subsequently

. The constituent lavers are rather uniform in thickness and consistency which facilitates symmetry of molding

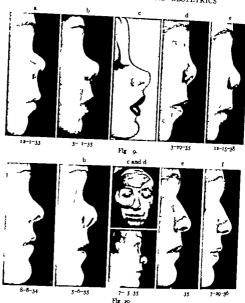

- Total blood supply is relatively greater and more easily trained to a narrow pedicle with ordinary precaution hesitancy of healing or slough is rare but can pribben
- 4 Th basic blush color will pensist or be early
- Flaps taken from other nonhair-bearing parts of the face will ha about the same qualties but of necessity will be much ama flor

Інарі

an als.

The tissues are relative ly flabby and, with the exception noted above unless supported are apt to shrink t an embar rasung extent

- 2. Such flam lack definite cleavage planes and closely adjacent areas may vary greatly in skin thickness and in the quality of the under lying turne all of which tend to negate both symmetry and sharpness of molding
- The total blood supply will average less, its sources are more diffuse. a greater number of operative steps may be required to establish an efficient pedicle, or even one of doubtful value
- In flans taken from be low the clavicle the basic red is deficient or absent however this can be at least partially com peneated by suitable injection of color intra dermally but will yield no variation in bl sh
- 5 The body hair may be negligible or so profuse a t require surgical depilation control with chemical depilatory scietors or razor

REBIES D. RESTORATION OF UPPER PART OF HOSE

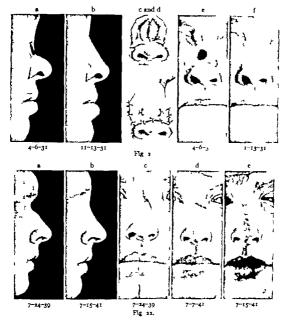

The cases selected for this and the following sense sine even greater emphasis: t be becausity for care determination of the real extent of loss or distortion and the mode and possibilities of repair before correction is instituted. Detortion of usable tissue should be entirely released before the flags are pot in place yet the preparation of delayed the control of the potential of the potential of the control of the control of the potential of the potential of the these real. We present the control of the control of the destination, corrected to an extension of the control of the deleast partial solution to the what and the how of this dilemma (see Figs. o and not of 5-b).

Forthead flags abould be cut wy exact. With unrestrained mulcialevaluar flags, an illustrate abould be made ( a shrinkage. An incidents around the cut made ( a shrinkage. An incidents around the cut made to the pass that it may be difficult to estimate bow much addition to any cyrello or its foundation will be really ecided. Here an overconvection can be dealt with by simple excision, while secondary additions are apt t be as complicated as the original implantation (Fig. 3)

Fig. 10. Overcorrection will subside after gut loop absorbs. d. The superimposed diagrams undicate the report flap and also the position of use The displacement of the right inner canthus as partially corrected at this time by burded sture. b and e, Final result. This required but operative steps with e, versal intervening.

The right time continue could have been brough I further mostally. The forthead effect is an overcome sensity by wide undermining and sature. The resisting uptile of the inner end of the right been could be further corrected by a "2" flap operation, but the patient shield to avoid this additional step. We have seen several such injuries doe trife wounds in soldiers. If both eyes were I tact, the man was grateful for the correction, but where one eye had been distroyed, he was apt to complain of the resulting narrow ed visual range of the remaining eye.

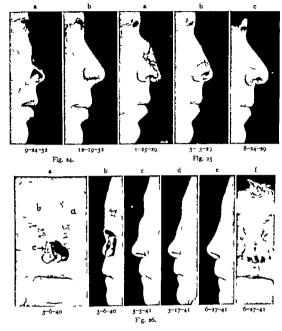

Fig 3. Ulcerations of face, mouth and pharynx, starting so years previously in a woman aged 43 years. a and c.

The use of the inframandibular or infraday icular flap gives no choice but for at least a two-step operation for affiring the flap attachment and final molding. Only the dorsal at tachment with corresponding thinning can be done at the time of transfer. The special thinning for the columella and alar infolding is of necessity postponed until after establishment of the new blood supply and the division of the pedicle (Fig. 31). The vestibule is lined and the columella formed by infolding

Saddlenose perforation theme can be, not lead to the perpending to the cheek, causing a distortion of the licentending to the outer can have \$A\$ too narrow and its port forcebased flap with right temporal periods as or The dutal end was split. The cheek car had been oranged as far as indicated in d, which was not far except Xad lining was obtained from the lower part of the fap. In auditions upper part better partially alleed the complex and lining was obtained from the lower part of the fap. months. The primary fault here as naking the forebast faple short and too narrow. A longer fap. will star possible or opening of the full length of the cost them to the greater width sould have brought days the property of the property primary factors and the star of th

of the extra length of the masal flap already provided for this purpose (Figs. 1 c and 18). In a nose intact above the vestibule asy needed lining can usually be derived from the original dorsal covering but no a total restoration an extra flap may be needed (8,a). It may be desirable but more frequently not practical, to make the columellar infolding sinde enough from above down to admit later a cartiage from above down to admit later a cartiage mon to total noses thus made (Figs. 20,1-26).

SERIES E. SUBTOTAL RESTORATION OF THE NOSE

Usually a sufficient amount of the nasal framework remains. In certain cases, restoration of the dorsal fine can be more easily attained by bone cutting than by cartilage implantation, but both might be used in a given case (Fig. 50). In all restorations, whether great or small, integrity of the fining is as important as the covering Restorations after total loss are done on the same lines but an extra small flap or garf may be required for fining of floor dor

sem, or both (co and &).

Fig. 24. a, Subtotal destruction of the nose by cancer
parts, in a woman 35 years old. b, Result 12 days after
repair with forchead flap for covering. The lining came
from turning in the remaining dorsal tissue. Repair coupleted in four operative steps over a period of 3 months.

Here a forchead flap gave a good dorsal line without

other support.

#### SERIES G. ARM FLAPS

Given a sufficiently bare area, a forehead flap may be cut to the desired size with little or no allowance for shrinkage (Fig 1 a) but for the arm or body flap (Fig 1 b) there is not only a natural tendency to shrink, for which some allowance should be made but the weight of the pendant pedicle tends to elongate the latter at the expense of width so that what at first appeared to be ample may have to be supplemented or the whole transplant discarded. It is for this reason that we cut an arm flap not only wider than apparently needed but make the pedicle even wider than the lateral extensions for the alae (Fig r b) The extra weight also demands more meticulous suture or an overlay of the borders of the flap to be adjusted later Supplementary elastic support of the looped pedicle by rubber band traction, anchored to collodion-affixed gauze patches, will greatly alleviate weight strain at the suture line

For comparison of adaptability see Table I and Figures 30 and 31

Fig 30. Sloughing arm flaps. Reactions still four-plus after four previous courses of treatment. Nose operation was uneventful after usable flap was secured (See discus-

non of case in Figure 10)

a, A diffuse alough in an inner arm flap after making both lateral incisions and complete undermining in one step. The flap was abandoned on account of diffuseness of the slough. In several of our earlier cases, with success attri buted to "foot's and beginner's luck, we raised large arm

but a proper delay will likely eliminate the difficulty 1 No flap should be transplanted the circulation of which had hesitated suffi ciently to cause blebs, deep discoloration or diffuse gangrene Such a flap would most likely not survive both thinning and transfer (Fig 30 a) We would consider worth while the attempt to use a flap that had suffered a sharply outlined distal loss from a frank gan grene provided the flap was still sufficiently

Amoderate activity of chronic across that frequently follows—train tri-or other meidental irregularity can assume be quieted and the patient made exercise by one exposure to radiation. I proper length and intensity

flaps in two steps, but a good routing is a minimum of three

b. Sharply outlined slough of a flap from the outer sur face of the same arm after incising and raising the flap in two steps, but still without dividing the lower pedicle Because the slough was sharply outlined and limited to a distal fourth, the flap was nursed along until it had completely healed without any suggestion of change or im paired circulation c, Spontaneous drawing in and healing of the damaged area, when the flap was successfully used with no hesitation of the circulation. Subsequent observations have forced the conclusion that in this and other losses, the fault was with the plan and not the tissues. This is also emphasized in the case of Figure 31 in which there

was no blood dyncraria.

Fig. 31 Partial raising at two sittings. At the time of application, circulation in the flap appeared adequate but it sloughed following implantation see a. b, Flap was taken down and allowed to heal with good circulation throughout the remnant. Fifteen months later with some secondary lengthening at the base, this flap was again put up, b, with no hesitation. The skin graft repair of the arm, shown in h, was done while awaiting recovery of the sloughed flap.

In c the transverse division of the healed in-place flap was at the level of the mouth slit. Higher than that is not safe as shown by the shortening which occurred after releasing the weight of the pedicle. (For discussion of case see Fig.

long or could be lengthened (Fig. 30 b) After a second hesitation the flap should not be used Forced abandonment of a flap at any stage is an embarrassment to the surgeon and more so to the patient. However loss of a transplanted flap is a catastrophe (Fig. 31)

Correction of deformities resulting from trau ma or disease. The first move in the repair of the donor area is the return and adjustment of the unused pedicle. After this has been transferred and the desired surgical correction made the remaining deficiency at the donor

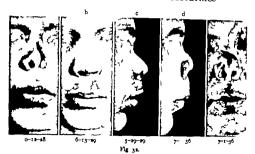

Fig 32. This case emphasizes the need of continual postoperative caution in any congenital or acquired infection.

Nasal and threat telementous for a years previous to recognition of the cause. Recent treatment of this po year old man had brought his blood reaction down from four to two-plus. a At our examination be had scarring of the pharyan and palate, internal nasal destruction and some full thickness loss. Medication was discount ed for a

site should be eliminated Granulating or rough scar must be camouflaged or hidden. The borders of small defects might be under mined and approximated, while others must be grafted. It is hardly practical to use a full thickness graft at the time of flap transfer A solit graft might be less conspicuous if drawn tight over a t or a week old bed of smoothly trimmed granulations as is our common practice on the forehead. On the trunk, residual disfigurements can be hidden by clothing which is also true of a man s arm. In a woman an arm flap should be taken preferably from the inner surface she can quickly acquire the habit of holding the damaged area close to the chest which makes a smoothly grafted area quite unnoticeable.

It is the exposed donor area of the forebead or arm and repair tissue that does not blend with the surrounding color that chiefly at tracts attention. It is very seldom that an infraclavicular graft or flap will have any of the natural facial blush after transfer but it may become more tanned than natural. No matter how perfect the technique, a marked color discrepancy will vituate an otherwise period before operative correction has undertaken, seour custom. We used to of orchead flage, one for listing to our four covering (Fig. 8). After these had healed in placto, we have been for rest and further intensit treatment. Latter is inserted cartilage graft into the derson, will be result shown in b and C. The length of their trusters was continued after cartilage insertion is uncertainty of returned y years latter with the weekage. Mach is about

quite acceptable result. Most women but for men will use cometics or surface stams. The natural red comes from the depths of the size and surface applications are but easily detected substitutes that lack the rue base coloring. To match free skin grafts and pedie flaps more nearly with the surrounding skin pigments can be instilled into the dema of transplanted skin with fine needle point (a)

On the forehead, the original split graft is later discarded for an evenly fitted full thek ness graft which is allowed to season before intradermal color is injected. The natural changing face-tinges are live and these cannot be duplicated even by color instillation, but this method is still our best substitute. The tenacity with which the transplant dings to the color characteristics of its source suggests the possibility of some intrinsic local control. For example, grafts and detached transplants taken from below the clavicle will in most instances, eventually lose all vestige of red, while flaps from cheeks or forehead, also pertaural grafts, will retain or regain their ast ural blush shade

# OBSERVATIONS ON THE TREATMENT OF ADENOCARCINOMA OF THE UTERUS

LAMAN A. GRAM M.D. Major M.C. A.U.S. Louisville, kentucky MILTON FRIEDMAN M.D., Major M.C. A.U.S. New York, New York, and WILLIAM S. RANDALL, M.D. Captain, M.C., A.U.S. Washington D.C.

N the past 3 years, 10 women with adeno-carcinoma of the uterus, comprising o 5 per cent of the patients on the gyneco-logic service have been treated at Walter Reed General Hospital These cases are presented without 5 year follow up for two reasons residual carcinoma was found in 6 of the 7 uteri which had received enormous doses of radium by means of the hysterostat designed by one of us (M F) and the presence of ovarian metastasis in 3 patients emphasizes the necessity for oophorectomy as part of the treatment.

Recent reports have suggested that panhysterectomy with bilateral salpingo-oonhorectomy should result in a 5 year arrest of 60 to 65 per cent of operable lesions (4 11) The impression that the 5 year survival rate may be increased to 70 or 80 per cent by the use of preoperative radium followed by hysterec tomy has been growing during the last 10 years. The majority of recent authors have advocated this combined method of treat ment. Because small doses of radium in the order of 1 500 to 2 500 milligram hours have relatively little effect on adenocarcinoma of the uterus conclusions drawn by authors who employed these small doses are of questionable value. The few reported cases treated with 4,000 or more milligram hours of radium are inadequate for a correct statistical evaluation of the combined method of treatment.

Conscaden (1944) reported 25 cases in which patients were treated with radium and hysterectomy in which the 5 year survival rate was 72 per cent. He recommended 3 000 to 4 500 milligram hours if given in one massive dose. Sheffey (1943) reported 30 cases in which patients were treated with

From the Waiter Reed General Hospital, Washington, D.C., and the Women. Surgical Section and Radiation Therapy Section of the Surgical Service and Pathology Section of the Laboratory Servica. combined therapy in which there was 34, per cent survival after 5 years. Only 9 of the 30 patients received doses of 4,000 to 5,000 milligram hours. In his cases of patient treated by surgery alone, the 5 year surviul rate was 18 it per cent.

Ward (1942) reported 37 cases in which combined treatment had been used with 648 per cent 5 year survival as compared with 659 per cent in 27 cases in which surgery slow was used. The radium dose varied from 2,000 to 4,000 milligram hours, followed by post

operative x ray therapy

Heyman (8) in Sweden (1937) reported 5 year arrest of 78 5 per cent of 65 cases in which treatment consisted of hysterectomy followed by radium and x ray therapy in 1941 (9) he reported a series of 402 including inoperable cases in which patients were treated with radiation alone, with a 5 year survival rate of 40 per cent. Included in the group were 156 clinically operable cases a which patients were treated only by raduation and in which the 5 year survival rate was 48? per cent. He did not employ the combined treatment of radium followed by hystered torny except in one subgroup of patients, who were operated on after radium therapy had failed in this group the survival rate was 46 per cent. The usual radium dose was 3,000 milligram hours delivered in two applications of 1 500 milligram hours at an interval of 3 weeks.

Brindley (1941) reported 24 cases with 79 per cent 5 year survival. He used the cambined treatment. The radium dose runed from 800 to 4,800 milligram hours, averages 2 600 milligram hours.

Miller (1940) reported 34 cases in which treatment consisted of radiation followed by surgery The 5 year survival rate was 74.5 per cent. Although he recommended preoperative x ray therapy only the exact number of patients so treated and the dose were not mentioned

Morton (1930) reported 18 cases in which the combined treatment produced a 66 per cent 5 year cure. Thirteen additional cases in which surgery alone was used had a 69 per cent 5 year survival rate. The dose of pre operative radium was not specified.

Healy and Brown (1939) reported 28 cases in which 3000 to 4000 milligram hours of radium was administered preceding hysterectomy. The 5 year survival rate was 70 per cent.

Ameson (t 1936) treated 10 cases with radium followed by hysterectomy to obtain a 5 year survival rate of 90 per cent. The dose of radium varied from 1600 to 4000 milli gram hours, 6 patients receiving more than 3000 milligram hours.

These published reports of a relatively small number of cases have been influential in determining the present trend toward combined therapy. The statistics in themselves are not conclusive. The recognized abilities of the authors however demand that their opinions be given careful consideration. Presumably, there are favorable clinical impressions of individual patients salvaged by the combined method which are not entirely reflected in the statistics.

In 1934 Sampson warned that a straight radium tandem in the uterun convity failed to irradiate the uterun homogeneously and that carcinoma localized in the cornu might be unaffected. In spite of his admonition the straight tandem continues to be widely used. Other methods of using radium in the uterus include multiple packing of loose capsules with strings attached or incorporation of capsulesing against pack (2). The capsules have been attached to wires (4, 5) in an attempt to fan out the radium. Several other devices have been designed (10, 16, 18).

#### RADIUM TECHNIQUE

The radium applicator which is called hysterostat was designed to achieve a more equable distribution of radiant energy to all parts of the uterus. Its construction was based on the following features:

Fig. 1 Dagman illustratum; intensity of radium energy distribution around platinum capsule. The greatest intensity is found along the side point A. The waket in tensity of radiation is located at point C which lies obliquely off the end of the capsule. A period hearn of weak radiation consendirective off the end of carsule to point B face Fig. 3).

I Study of the distribution of radiation energy around a radium capsule with a wall thickness (filter) of 1 or 15 millimeter of platinum reveals certain data of utmost importance to successful use of radium in the uterus

a. The greatest intensity of radiation is found along the side of a radium capsule (point A Fig. 1) due to a filtration factor and a distance factor Most of the rays emanating from all points along the radium source travel obliquely through the metal wall of the capsule to reach point 4 The longer path through the wall of the capsule which the oblique rays must traverse subjects them to in creased filtration in the metal wall. However this increased filtration is at a minimum for point A as compared with all other points equidistant from the outer wall of the capsule (point C for example) In addition, the average of the distances which the rays traverse from each point along the radium source to reach point A along the side of the radium capsule is shorter than for point C or any other point equidustant from the wall of the capsule

b The weakest intensity of radiation from a linear radium capsule is located at a point obliquely off the end of the capsule (C Fig 1) because the average distance which the rays, from each point along the radium source travel is longer than for point A Furthermore many of the rays traveling obliquely through the wall of the capsule to reach point C must traverse eight or more times the stated thickness of the metal wall before emerging from the capsule. Thus the high filtration considerably decreases the intensity of the total radiation reaching point C

c. Radiation coming directly off the end of a linear radium capsule to point B in Figure 1 is filtered only with the minimum stated filter of 1 or 15 millimeters of platinum. This advantage is neutralized by the fact that the average distance which the rays traverse from each part of the radium source is the longest of all the average distances. As a result, a natrow pencil of increased

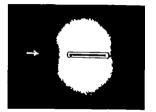

Fig. 1 Actual picture of radiation intensity distribution made by placing a radium capsule against an unexposed film suspended in air. The radium element source is centimeters long and the wall of the capsule is 5 mills meters of platinum. Note the great i tensity furalisation storage the side of the radium capsule, and the equally striking weakness of the radiation counts of the red of the label of the radiation counts of the red of the label of the radiation counts of the radiation counts of the radiation that the long radiation counts of the radiati

radiation intensity comes off the end of the capsule (see arrow Fig. 2)

- d. The great intensity of radiation along the side of the radium capsule, and the equally striking weak ness of the radiation coming off the end of the capsule are illustrated in Figure : These facts are significant when the unsue to be irradiated comes in direct contact with the radium sources, in the treat ment of convence carponers.
- 2 When several capsules are placed per pendicular to a surface the intensity of radiation reaching that surface will be rel attively small. In Figure 3 although 2 capsules are pointed at the cornu it receives less radiation than those parts of the uterine wall in direct contact with the sides of the capsules.
- 3 For effective radiation of the fundus of the uterus one or more radium capsules must be flat against it Several tandems or individual capsules pointing at the fundus per pendicularly will not provide comparably effective radiation. The crosspiece of the hysterostat permits proper placement of radium against the fundus (Figs. 4 and 5) and can be adjusted to provide contact with a concave fundus (Fig. 12).
- 4. Studies of energy distribution around radium sources, according to the Paterson Parker dosage system for gamma ray ther apy' (14) indicate that radium sources should be placed pempherally around an area which is

Fig. 3. Self exposed photograph saids ith lysematic containing 6 radium expusies, as in Figure 10 the thetical technocanal by continenters long. Although the cappiles are polaried at each coren, the caines of pasilion intensity in the cornu is readily apparent. The healt importations is effectively irradiated by the continent of the midpoint of the triangle in the continent of the triangle is the continent of the continent of the continent processary.

to be homogeneously irradiated, within certain spatial limitations. The addition of multiple sources within the center of this area (packing a uterine cavity with multiple radium capsules) serves to increase the intensity of radiation within the center of a cavity when it is already high (Fig. 3).

5 The hysterostat is constructed of multiple sections which can be screwed together in the operating room after the contour of the uterus has been defined so as to produce is roughly triangular distribution of radium sources within the uteruse cavity. Each section in the length of a single radium crisis Sections in two angulations (170° and 167) are provided so that a uteruse cavity of shoot any size or irregular configuration can be fitted (Figs. 5a b c). The crossplere (Igs. and 5) is so arranged that it can occup for different predetermined angles in relation to

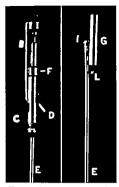

Fig. 4. The crossolece. The handle end is on the left, the radium end on the right. The flange, B is attached to knob only and stides into the limiting alors, D in the revolving sleeve C. The flange must be pulled below the fixed guard, F before the sleeve can be rotated. E. Tubular stem through which runs the central view.

At the radium end of the crosspices is the shell, G which can be unacrewed and a radium capsale inserted. This can be made any desired length by adding extra straight or anyolar pieces. The shell is attached by a hinged joint, I to the end of the tubular sterm, E. The central wire emerging from the tubular sterm is attached to one end of the shell by means of an axis g joint L.

the supporting stem. Four side-pieces are provided but only two of them are needed except in unusually large uteri

The sheaths which contain the radium capsules are constructed of monel metal tubing with a wall thickness of 0.4 millimeter which provides an ideal secondary filter. These sheaths can be constructed to contain radium capsules of different sizes. We have employed two sizes, 4 by 23 millimeters and 6 by 18 millimeters.

6 The radium dose which we employ has been arrived at by empirical means. Calcula tion of the distribution of the radium energy to various parts of the uterus in units of gamma roentgens has not yet proved to be of practical value in ascertaining the desired radium exposure of a particular uterus under treatment.

The individual capsules contain 10 or 15 milligrams radium with a primary filter of 1

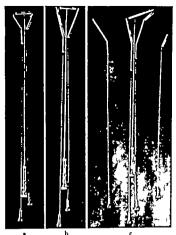

Fig. 5 Crosspiece and lateral tandems arranged in 3 different hypothetical distributions. a, Arrangement of 4 capsules in a uterine cavity 5 centimetres long. One lateral tandem is angulated by bending the flat stem. b Arrangement of 6 capsules in a uterine cavity 7 centimeters long ment of 6 capsules in a uterine cavity 7 centimeters long. This has been accomplished by inserting an extra section into each lateral tandem. c Arrangement for a large it regular uterms cavity. The additional 2 lateral tandem are available in case a large uterine cavity can accommodate them. Note that each arrangement of the applicators provides one radium capsule in the cervical canal.

or 15 millimeters platinum and a secondary filter of 0.4 millimeter of steel A dose of 1 000 milligram hours per capsule is given when the uterus is normal in size A small uterus with a cavity 5 centimeters long holding four capsules will receive a total dose of 4 000 milligram hours given in one treatment. If the uterus is larger and contains more radium capsules the individual dose per capsule is from 700 to 1 000 milligram hours. The total doses in this series ranged from 6 000 milligram hours to 12,480 milligram hours.

Generally when the uterus is larger than normal and the total dose is to exceed 5 000 milligram hours radium is given in two treat ments at an interval of 7 to 10 days. The

Fig. 6 Case t Blopsy before -ray therapy This growth is classified as a moderately undifferential red above carcinoma originating in the endocervical glands. The tendency to form liveola struct res is clearly shown. X61.

uterine canal usually shrinks and its shape changes after the first treatment so that the rational treatment is the second treatment.

This technique had been employed in 28 cases by one of us (M F) in civilian life prior to 1942. The radium exposures in half of

these ranged from 6 000 to 10 230 milligram hours. These cases will be the subject of a future publication

Several other devices have been designed for the purpose of obtaining diffuse distribtion of radium energy throughout the items. Schmitz using a Y shaped applicator administered doses up to 6 coo milligram from. Kaplan employing a ring applicator administered doses ranging from 6,000 to 7,00 milligram hours.

#### CASE REPORTS

Case I Moderately undifferentiated adencer cinoma of the cervix, slightly advanced.

A moderately well nourished white featie, and 30 years was admitted to the hospital Spremberl, 1944, complaining of intermensitual bleeding in months. She had one child aged 17 and had had or miscarriage 2 years ago. Memses were regular very 28 days lasted 7 days, with moderate for und pain. Six weeks before admission the patient savel a mass protruding from the vaginal onfer, its disappeared when she lay down.

On examination, the abdomen was flat and set, with no masses or tenderness. The vagion was on mal. Protrumeters in diameter with a red muscle surface which bed easily. The uterus was of tusual size anterior and free. Ovaries were zone. There was no induration in the torout legisler.

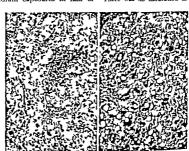

Fig 7 Left, Case Biopsy 8 days after x-ray treatment started (3 days after completion of tumor dose of 3,000 delivered over period of 5 days). There are slight to moderns radiation effects, predominately never hyperchromatism and to less extent cytoplasmic as ell-

ing X70.
Fig 8. Case Another area of section shown in Figure 7 Here the radiation effects are much more striking. X70.

Fig. 6. Case r. Entire uterine cavity showing granulating endocervical surface at site of tumor. The upper portion of the corpus appears relatively normal.

Blops, of the endocenycal tumor showed moder attly undifferentiated adenocarcinoma (Fig. 6). Supervoltage x ray therapy was given with ravs activated at 1 000,000 volts over a period of 15 days activated at 100,000 volts over a period of 15 days. The skin dose ranged from 1,000 ft or 5 gor to each of 6ve skin portals. The tissue dose delivered to the tumor in the cervix was 3,040 r.

Three days later (18th day after initiation of treatment) the cervical tumor had shrunk about 20 per cent and measured 4 centimeters in diameter. The uterine cavity was curetted and the tissue 30 being proliferative endometrium. The cervical tumor was excised with endothermy A radium tandem composed of 3 platinum capsules totalling 60 milligrams of radium was introduced into the uterine cavity, and three cork, each of 15 milligrams radium were placed in the vagina about the cervix. A total dose of 8 000 milligram hours was given.

Microsopic examination of the cervical tumor (Firs. 7 and 8) revealed in response to 3 030 r extensive destruction of tumor cell. Those remaining howed moderate to marked changes pred minantly nuclear alteration—and to a lesser degree swelling and vacuolation of the cytopla m.

Sixty five days after railium abdominal pan hysterectomy and bilateral salpingo-on bottertomy were performed the Richardon technique being used. The peritoneum and intestines were remained allowed to reduce the mentaged lymph nodes or induration were present. The uterus was small and attrophic (Fig. 9) as were

Lig to Case 1 Section I cervix near external orifice showing nests. I residual carcinoma deep in the wall, X too.

the tubes and ovaries. There were no adhesions. The jistoperative course was entirely uneventful and the patient was discharged on the 18th day.

The excised uteru was examined microscopically and islands of residual carcinoma were seen in the endocervix near the external os (Fig. 10)

Five months after operation, the patient was thin and complained of diarrhea and frequency of urination. There was moderate induration at the apex of the vagina with marked redness and vellows high discharge.

This case demonstrates that roentgen therapy can contribute effectively to the destruction of the undifferentiated forms of adenocarcinoma. On the other hand, a large radium exposure (8 ∞∞ mgm hr.) failed to destroy all the tumor in the cervical myometrum.

CASE 2 Undifferentiated carcinoma of corpuuters advanced

This patient aged 6 years white was admitted on lugu to 1011 compilating of irregular vaginal bleeding for 0 month. Lighteen years previou Is he had received radium for a fibroid turn of the uteru. I llowing which her menses ceased. She had had 15 children.

The patient was semewhat obese and her blood pies ute was 100 100. The cervix was molerate in the firm and closed. The uterus was four times normal ite enlarged more to the left and freely movable. No a linexal masses or induration were detected.

It time I curettage the uterine canal mea ured 12 4 centimeters and contained a large amount I yellow frable to us which proved to be undifferentiated a lenocarcinoma on hi tologic xamination (lig. 11).

Fig. 6. Case Buopsy before x-ray therapy. This growth is classified as a moderately modificerentiated denocardnooms originating in the endocervical glands. The tendency t form alveolar structures is learly shown. X61

uterine canal usually shrinks, and its shape changes after the first treatment so that the radium must be rearranged for the second frestment.

This technique had been employed in 28 cases by one of us (M F) in civilian life prior to 1042. The radium exposures in half of

these ranged from 6,000 to 10,230 milligram hours. These cases will be the subject of a future publication.

Several other devices have been designed for the purpose of obtaining diffuse distribution of radium energy throughout the utras. Schmitz, using a 1 shaped applicator as multistered doses up to 6 oco miligram born. Kaplan employing a ring" applicator administered doses ranging from 6,000 to 7,900 milligram bours.

#### CASE PERCETS

CASE 1 Moderately undifferentiated adenous cinoma of the cervix, slightly advanced.

A moderately well nourahed white female and 30 years was admitted to the hospital Spetiment, 1944, compliating of intermensional beforeing ferj months. She had one child aged 17 and had had well as the state of th

On examination the abdomen was that and sigwith no masses or tenderness. The vagina sais so mal. Protruding from the cervis was a hard, consider mass, 5 centimeters in diameter with a red grands surface which bled easily. The uterus was of its usual size, anterior and free. Ovaries were normal There was no induration in the broad lignment

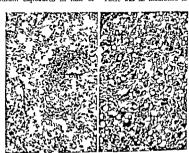

Fig. 7 Leit, Case Biopsy 8 days after -ray treatment started (3 days after completion of tumor dose of 3,050 delivered over period of 5 days). There are algebt to moderant radiation effects, predominately nuclear hyperchromatism and to less extent cytoplasmic sacil-

ing, X70.
Fig 8. Case Another area of section shown in Figure 7 Here the radiation effects are much more striking X70.

Fig 9 Case r Entire uterine cavity showing granulating endocervical surface at site of tumor. The upper portion of the corpus appears relatively normal

Blops) of the endocervical tumor showed moder ately undifferentiated adenocarcinoms (Fig 6) Supervoltage x ray therapy was given with rays activated at 1,000 000 volids over a period of 15 days. The skin dose ranged from 1000 r to 1500 r to each of five skin portals. The tissue dose delivered to the tumor in the occevix was 3,050 r.

Three days later (18th day after initiation of treatment) the cervical tumor had shrunk about 10 per cent, and measured 4 centimeters in diameter. The uterine cavity was curetted and the tissue obstained was beingin proliferative endometrium. The cervical tumor was excised with endotherms. A radium tandem composed of 3 platinum capsules totalling 60 milligrams of radium was introduced into the uterine cavity and three corks each of 15 milligrams radium were placed in the vagina about the cervix. A total dose of 8 000 milligram hours was given

Microscopic examination of the cervical tumor (Kry 7 and 8) revealed in response to 3 oper exten we destruction of tumor cells. Those remaining showed moderate to marked changes predominantly nuclear alterations and to a lesser degree swelling and vacuolation of the cytoplasm.

Sixty five days after radium abdominal pan hysterectomy and bilateral salpingo-cophorectomy were performed the Richardson technique being used. The peritoneum and intestines were normal no enlarged lymph nodes or induration were present. The uterus was small and atrophic (Fig. 9) as were

Fig. to Case. Section of cervix near external onfice showing nests of residual carcinoma deep in the wall \$130.

the tubes and ovaries. There were no adhesions. The postoperative course was entirely uneventful and the patient was discharged on the 18th day

The excised uterus was examined microscopically and islands of residual carcinoma were seen in the endocervix near the external os (Fig. 10)

Five months after operation, the patient was thin and complained of diarribes and frequency of urina tion. There was moderate induration at the apex of the vagina with marked redness and vellowish discharge.

This case demonstrates that roentgen therapy can contribute effectively to the destruction of the undifferentiated forms of adenocarcinoma. On the other hand a large radium exposure (8 000 mgm hr.) failed to destroy all the tumor in the cervical myometrium.

CASE 2 Undifferentiated carcinoma of corpus uten advanced

This patient aged 6 years white was admitted on August to 1044 complaining of irregular vaginal bleeding for a month. Fighteen years previously she had received radium for a fibroid tumor of the uterus following which her menses ceased. She had had 3 children.

The patient was somewhat obese and her blood pressure was 100/100. The cervic was moderate in size firm and closed. The uterus was four times normal size enlarged more to the left and freely movable. No adnexal masses or induration were detected.

At time of curettage the uterine canal mea ured 12 5 centimeters and contained a large amount of yellow frable tis ue which proved to be undiffer entiated adenocarcinoma on histologic examination (Fig. 11).

Fig Case 2. Section of tumor before therapy show up an extremely oddifferentiated carrinous. The cells are compactly arranged in solid sheets—the thin vascular trabeculae coursi g throughout. X63.

The first radium treatment was given on August 18 1041. By means of a three piece bysterostat, 22 capsules of 10 milligrams each were inserted in tri angular arrangement. The dose was 5 760 milligram hours (Fig. 12).

Fifteen days later another curettage was per formed preparatory to the second radium treatment. The uterus had shrunk, the canal now measuring 9 centimeters. A large amou tof yellow frable cheffy necrotic tissue was removed apparently from every portion f the conjust. Histologic examination of this tissue revealed considerable necrosis of the tumor cells, but some islands in the

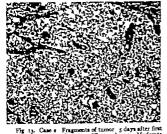

Fig. Case's Pragmont on timory Suys Med. Institution Training and vaccolation of the cytoplasm are noted in area shown. In other fields moderately differentiated papillary pattern was noted showing milder radiation effects. X69.

Fig. 2. Case 2. Roentgenograph of hystroset cataining 1 radium capsules. First radous treatest Uterine canal 12.5 centimeters long, funda 4; custmeters wide, irraduated with angular crosspice.

undifferentiated portion of the tumor shored moderate swelling and vacuolation of the cytopher (Fig. 13) A few areas with a differentiated papeling pattern, not seen in the original biopsy shored ittle effect from radiation.

With the three-piece hysterestat in a different, but still transgular arrangement, 12 appeles of milligrams each were inserted in the steres and dose of 6 yes milligram hours was administed. The total exposure in the two treatments as 11-10 milligram hours.

Forty-four days after the second indian time ment, panhysterectomy and blattend alpide-ophorectomy were performed. The peritocent in intestines appeared normal There were no share lymph nodes along the sorts or beneath the peritory brim. The uterus was smaller than normal streetly moveshed both tubes and various eraphic. In pulling up the uterus, moderate testing used, the uterine veins were toon on either and considerable bleeding ensued. The vein erather small but thin welled and frishle. The purmetrial thances were moderately frishle and survey had a tendency to test through the time. Pepot operative course was uncernful and the patient as

discharged on the 19th day

Histologic examination revealed no endered de residual tumor in the uterus, tubes, or ovares. The

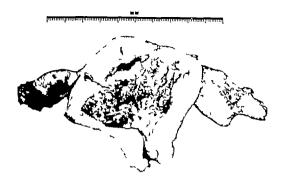

Fig. 14. Case s. Uterus removed 44 days after second radium treatment. Total dose of a treatments 13,450 milligram hours. Note hemorrhagic and necrotic membrane completely covering the uterine cavity

uterine cavity was lined with a thick hemorrhagic and necrotic membrane (Figs. 14 and 15)

Two months after operation the patient com plained of increasing pain radiating down the back and side of the left leg and there later appeared marked edems of the leg. Six months after operation a firm fixed mass was felt in the lateral left lower abdomen above the inguinal region also edema of the left arm the cause of which had not yet manifested itself.

There are several distinctive features to the case. The first radium dose of 5.760 milligram hours which is ordinarly considered adequate for an undifferentiated tumor was ineffective in that moderate radia ton effects were seen in the undifferentiated part of the tumor but only slight effects in the differentiated part. Shrinkage of the uterus brought the pe ipheral portions of the tumor closer to the radium sources during the second radium administration. The reduction in length of the uterine canal from 12 5 centimeters to 6.5 centimeters is noteworthy.

The total radium dose of 12,480 milligram hours is remarkably large and apparently effectively eradicated the uterine tumor

CASE 3 Moderately undifferentiated adenocar cinoma corpus uters, advanced

This patient white aged 54 years was admitted March 10 1944, complaining of continuous vaginal bleeding for 2 months. Menses had been normal and regular until menopause April 1943. She had had 2 children.

The patient was in fair general condition. Bulging from the cervical canal which was idiated to about 4 centimeters was a grayish red granular finable tumor attached to the posterior and right alteral surface of the endocervix and extending well up into the uterus. The corpus was two and one half times normal size in midposition and free

Fig 15 Case 2 Typical section of uterus shown in Figure 14. Note the organizing hemorrhapic membrane resting directly on the compact, atrophic myometrium No residual carcinoma found in this case. X47

Fig. 6 Case 3 Curettage before therapy aboning typical zon of moderat by ndifferentiated admons choosa. While there is a definite abvolar rrangement, in many areas th cetla are grouped in compact masses the frequent abnormal mitoses. X63.

Posteriorly on the right side there was slight thick ening. Biopsy revealed moderately undifferentiated adenocarcinoma (Fig. 16)

The presenting tumor was curetted. The canal was 9 centimeters long. 1 three-piece hysternata: containing to capsules of 15 milligrams of radium each was introduced into the uterite cavity (Fig. 17). A dose of 6.450 milligram hours was given.

The second radium treatment 8 days later consated of the introduction of three cords containing a total of 55 milligrams of radium; the vagina against the cervix. The dose was 300 milligram bours The t tal radium dose was 10 110 milligram hours

Fig. 8. Case 3. Curettage 18 days after 6,450 milligram hours intrauterine radium showing one of several nests of residual, moderately undifferentiated carcinoma. There is slight radiation effect. X63.

Examination at the time of the second mains in treatment aboved the cervit to be of moderite are and deserd. The ut rus was twice normal are at the continued to the continued and the continued and the continued as the continued

Thirty nine days after the vaginal radius treatment, panhysterectomy bilateral salpingo-copie rectomy and appendectomy were performed Catheters had been placed in the ureters. The peritoneum and intestines appeared normal, Osc lymph node a centimeters in diameter was denete adherent to the aorta, 4 centimeters above the lead of the umbilicus, and was not exched. One hope node in the right hypogastric area I centimeter # diameter was excised. The uterus was slabily colarged and irregular The tubes were normal. The right ovary was 5 centimeters in diameter sighth vellowish with a thickened capsule the left ovar) was atrophic. The right uterine vessels aere heated far laterally laying the ureter to the side and taken the broad ligament tissues on the right. On the left, a conservative approach was made going struck down along side the cervir. The patient was dr charged 36 days after operation

Charged 30 days after operation

Histologic examination of the excised tasse revealed small islands of viable-appearing cardinass

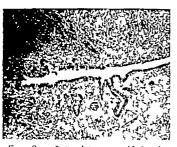

Fig. 10 Case 3. Section of uterus removed 81 days after intrusterine dose of 6,450 milligram hours and vagmal dose of 3,500 milligram hours radium showing one of the readual neoplastic foci indirecting the myometrium. The secolastic cells form tubular structures and show moderate radiation effects. ×63

infiltrating the superficial myometrum in 8 of 10 blocks taken from the corpus (Fig. 10). In the right orary there was a cysuc, metastatic lesson 3 by 3.5 centimeters (Fig. 20). The hypogastric lymph node showed hyperplasia but no carcinome.

A postoperative course of roentgen therapy (1,000 000 volts) was given to the pelvis The kin doce was 4,000 to each of four pelvic portals. This delivered a tissue dose in each broad ligament of 3 to rover a period of 72 days. Subsequently a second course of roentgen therapy was delivered through four portals crossfiring the pracortic node like kin dose was 4.23 000 the tumor dose 5,400 r. There was no evidence that this node contained metastatic carcinoma. Eleven months after operation the patient felt well and was quite active to the patient felt well and was quite active.

The intrauterine radium dose was 6 540 milligram hours followed by a vaginal radium dose of 3 960 milligram hours. Nevertheless 81 days after the intrauterine radium treat ment, the superficial layers of the myometrium were infiltrated by residual carcinoma which was differentiated in the form of tubular structures.

Case 4. Moderately undifferentiated adenocar curoma corpus uten, early

This patient, aged 50 years white was admitted on July 23 1944, complaining of moderate vaginal bleeding on one day July 16 1944. Menopause had over the second of the second years of age.

The patient was of moderate build The vagina was thin with some varicosities The cervix was small and reddened about the closed os The uterus was small, in midposition and free there was

Fig. 20. Case 3. Metastatic popillary cystic lesion in right ovary lined as th large polygonal and columnar cells showing bearire nuclear changes. The pleomorphism and the nuclear alterations re-probably the effects of radia tom ×45.

no adnexal mass or induration. The uterine canal measured 6.5 centimeters at the time of curettage Many small pieces of gravish white tissue were removed.

Microscopic examination showed moderately undifferentiated adenocarcinoma (Fig. 21) generally forming large glandular structures but with occasional scattered compact groups of neoplastic cells and a moderate number of mitotic figures

One week later radium was introduced into the uterine cavity with a 3 piece hysterostat that con tained 6 capsules of 1 smillgrams cach. A total dose of 6 6 300 milligram hours was given. This represented a dose of 1 005 milligram hours per capsule

Forty five days after the radium treatment, pan hysterectomy and bilateral salpingo-cophorectomy were performed. The peritoneal surfaces and in testines appeared normal. No enlarged I, mph nodes were felt along the aorta or under the brim of the pelvis. The uterus was small the tubes and ovaries atrophic. The tusues of the broad ligaments cardinal ligaments and vagina were friable and easily torn. The postporerative course was complicated by partral intestinal obstruction and an abacess in the abdominal incision. The patient was ducharged 35 days after operation.

The aterine wall averaged from 15 to 2 cents meters in thickness and the cavity was lined through out with a creamy yellowish green necrotic mem brane, 7 to 2 millimeters thick. In 4 of 7 blocks residual carcinoma in the superficial myometrium formed large glandular structures with an occasional island of undifferentiated cells showing moderate swelling of the cytoplasm (Fig. 22). In other areas, deep in the myometrium were seen numerous small spaces some partially lined with neoplastic cells of bisarre form.

Fig 2 Case 4 Blopsy before radium slowing moder tely undifferentiated adenocarcinoma. In other fields more solid medallary arrangement of the cells was seen similar to that noted along one edge of the photomicrograph ×63.

Five months after operation the patient felt well and was fairly active. There were no masses or tenderness in the abdomen, and the incision was well healed. The vagina was slightly thickened at the apex. The broad ligaments were soft

CASE 5 Undifferentiated adenocarcinoma of

This patient, aged 50 years, white was selected on August 31, 1032 complaining of brownich right discharge defly for a year She continued to no structe regularity every 28 to 30 days. The flow was moderate, without pain, and lasted; days. See hal 2 children the youngest 23 years old

Examination showed a well nourshed paired. The vaguas was normal. The cerrur was of modern size with two munute polyps on the posteror by The uterus was twice normal size, irrepair he et line anternor and free. The right oway continues amail cyst 4 centimeters in diameter the left surp was atrophic. There was no induration in the petric was atrophic.

Under anestheria, the polyps were exceed Inuterine canal measured 9 centimeters. The cirily was gently curretted. A large amount of frails graular graythy yellow (tissee was obtained, apparent from every part of the corpus. Microscopic raints ton showed the cervical polyps to be being itendometrial tissue was for the most part unide entiated adenocarcinoms (Fig. 3) while is a ferfragments, the neoplastic cells were differentiary into glandplus structures (Fig. 24)

Intracavity radium was administered that piece bysterosist, containing to capacie of in milligrams seed. Fig. 3). The uterase cavity sularge the canal being 9 centimeters lang, and the fundus 3 5 centimeters wide. Fig. 23. Case 5 Curettage before therapy showing complete undifferentiation present in parts of the tumor X63

Thirty-eight days after the radium treatment pathysterectomy and bilateral salpingo-ophorectomy were performed. The peritoneum and in testines were normal. No enlarged acritic of hypogastric lymph nodes were palpable. The uterus was slightly enlarged and free. The tubes and ovaries were attophic. The cardial ligaments and vaginal tissues were alightly edematous and felt fragile but no technical difficulty was encountered. The post operative course was uneventful, and the patient was discharged after as desp

The cavity of the uterus was somewhat expanded with the canal measuring 7 5 centimeters (Fig a6) Extending upward from the internal os was a pseudodiphthentic membrane 3 by 4 centimeters in diameter and 3 to 4 millimeters thick. The upper posterior wall of the corpus was covered with a hemorrhagic membrane Sections taken through the lower portions of the corpus revealed extensive car cinoma deep in the myometrum the surface being covered with the thick pseudodiphtheritic mem brane. Similar carcinoma infiltrating the myometrium was found in sections from each cornu, occurring for the most part as infiltrating sheets of cells, with little tendency to form alveolar structures. The effects of irradiation were mild to moderate, and included slight swelling of the cytoplasma and the presence of a moderate number of bixarre nuclear forms (Fig 27)

Seventeen months after operation, the patient felt better than she had in years, and had gained 15 pounds. The abdomen was soft The vagina was thin and pale, somewhat shortened, well healed and with no residual thickening. The broad and utero-acral ligaments showed no induration.

This is a case of predominantly undiffer entiated carcinoma similar to that in Case 2 in which a radium exposure of 7 000 milligram

a definite tendency of the cells to form glandular structures. Compare with Figure 23 ×63

hours failed to destroy the carcinoma completely

Case 6 Moderately differentiated carcinoma of corpus uteri moderately advanced

This patient aged 35 years white was admitted on December 31 1944 complaining of vaginal bleeding which had continued for 18 months. Men arche occurred at 14 with intermittent menses until she was 16 when they ceased completely. In August, 7043 when the patient was 33 vaginal spotting began. After February 1944 bleeding became almost constant. She had had dyspnea on exertion since youth

Fig 25 Case 5 Hysterostat containing 10 radium capsules of 15 milligrams each Utenne canal measured 9 centimeters long fundus measured 35 centimeters wide. Crosspice contained two capsules.

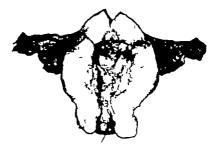

Fig. 26. Case 5. Uterus removed 38 days after 7,000 selfigram hours of radium. Note the thick necrotic membrane covering the endometrial surface except ! a triangular area on the posterior wall not covered by the hysterostat.

The patient was slender Mitral stenosis with cardiac Insufficiency was evident. The cervix was rather small, the os slightly dilated with a minute polyp high in the canal. The uterus was anterior slightly enlarged symmetrical, and freely movable Both ovaries were normal in size and were free

At time of curettage the uterine canal measured 8 centimeters. A large amount of friable, yellowish tlasue was obtained apparently from every portion of the interior of the uterus. Intracavity radium was administered with a 3 piece hysterostat con

taining 7 capsules of 10 milligrams of radom eck. A total dose of 7,000 milligram hours was give Microscopic examination of the endorstram it was a milligram to the endorstram in the capture of the endorstram in the capture of the endorstram in t

Fifty five days after treatment, pathwisteretary and billateral salpiopo-cophorectomy are promed. The pertioneum and intestines appeared formed. There were no enlarged sorts or bregastre lymph nodes. The uterus as small 1 moderately atrophic both tubes and orares we atrophe. There was no technical difficulty in operation. The excessed uterus (Fig. 20) was small and firm with a narrow tubular canal, appearing the entire term of the continued of the cavity were lord with ferred granulations. There was no peudodylatethe membrane. Microscopic examination showed by 1 of 6 blocks neoplastic glands inflittuating the nemertum. The effect of irradiation on the lining the alweed was insignational (Fig. 20).

The postoperative course as completed by prolonged diarrhea and painful frequent gates toon. After a months, the tissues at the aper of the vagina separated and formed an aker 3 continues in diarreter. There was industion around the ulcer particularly beneath the bladder.

The uterine cavity was not large the radium distribution and dose (7,000 millerin hours) was adequate according to our oral concept of dosage but there was readial carcinoma infiltrating the myometrium.

CASE 7 Moderately differentiated adesocardnoma of corpus uteri, advanced.

Fig 28. Case 6 Fragments removed at time of diagnostic curettage composed of moderately differentiated neopartic glands infiltrating the myometrium ×63.

This patient aged 67 years white was admitted on August 15 1044 complaining of pink mucoid discharge for 18 months. The patient had four children, the youngest 22 years old. The menopause had occurred 20 years ago. One year ago. 6 x ray treatments given elsewhere stopped the pinkish discharge for 4 months.

The patient was obese and had hypertension (200/110) and arterioscierosis. There were no abdominal masses or tenderness. The mucous membrane of the atrophic vagina was red the cervix was small, firm and red The uterus was in midposition and two one half times normal size. No adnexal mass or lodgration was felt.

At time of curettage the uterine canal measured 8 centimeters. Microscopic examination of the tissue obtained revealed moderately differentiated in filtrating adenocarcinoma (Fig. 31)

One week later a 3 piece hysterostat was inserted containing of capsules of ro milligrams radium each. The dose given at this first radium treatment was 4500 milligram bours. Eight days later the patient deeped pelvic celluluts, and at this time there was moderate induration in the rectovaginal epitum and marked induration in the left broad ligament. The temperature and discomfort gradually subsided and the patient was discharged. Per sistent pelvic induration caused the second radium treatment to be deferred.

Seventy days after the first radium treatment the patient returned with no complaints and no bleed mg. Penkeillin was given prophylactically for 5 days. Under anesthesia the uterus was one and one-half times normal size and fairly movable. There were no palpable adnexal masses but there was some thickening in the left uterosacral ligament. The uterus was thoroughly curetted. The endome trium was scant and the interior of the uterus was quite rough to the curette. At this time the uterine

Fig 20. Case 6 Uterus and adness 55 days after 7 000 milligram hours of radium. Note the small uterine cavity covered with a granulating membrane

canal measured 65 centimeters. A 3 piece hystero stat containing 8 capsules of 10 milligrams radium each was inserted and a dose of 4,400 milligram hours given (Fig. 32). The postoperative course was uneventful.

Fig 30. Case 6 Low power showing one of the several residual areas of carcinoma infiltrating the myometrium.

Fig. 3. Case 7. Blopsy before therapy showing moder tely differentiated adenocarcinoma infiltrating the myometrium. ×63.

Curettage 75 days after the first treatment of 4 500 milligram hours dislodged only a few fragments of tissue however they consisted mostly of per sistent adenocarcinoma infiltrating the myometrium and showing no demonstrable effects of ir radiation.

Eight months after the first radium treatment the patient felt weell except for occasional bearing down sensations in the lower abdomen. The uterus was smaller than normal pelvic induration had didninabed Panhvaterectomy and bilateral sal pingo-oophorectomy were performed. The operative

Fig. 33. Case 7. Uterus 6 mo the after second radium treatment. Uterine canal now measures 4.5 centimeters long (original length 8 centimeters). Not the uterine carity completely lined with shaggy necrotic membrane.

Fig. 32. Case 7 Second radium treatment. Derect canal has shrunden to 6 5 centimeters in length and L-7 to 7 centimeters in width. Hysterostat see occurs capsules of o milligrams each. Dose 4,160 milligram kest. Total dose, 2 treatments, 8,000 milligram least.

procedure was complicated by numeror proinflammators adhesions. There was marked threesalpingstis, with moderate industrion of the wosacral and left cardinal ligaments fixing the story deep in the prelivis.

The uterus was small with a canal 45 cet meters long. The cavity was completely lined 194

Fig. 34. Case 7. Section of terms shown in Figure 11 ith residual careinoma deep in the myonetrum.

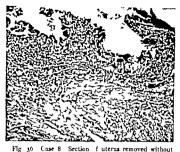

Fig. 3. Case 8. Fragments from diagnostic curettage made up entitlely of solid maness of large polygonal neoplastic cells similar to the arrangement seen in Cases 2 and 5. In other areas the cells are differentiating into large sandolar structures. Mitoses are numerous throughout ith many almormal forms. This is classified as a moder stely undifferentiated adenocarienoms. X60

shagy membrane beneath which patchy areas of organization were seen. The invometrium was not significantly thinned and the vessels were prominent (Fig. 33). Microscopic examination of 14 serial, cross-section planes through the entire uterus revealed tumor in a sections of the midcorpus. The tumor was present as elongated glandular structures deep in the myometrium in one (Fig. 34), while in the other the neoplastic cells were arranged in a solid nest.

The patient received a total dose of 8 gco milligram hours intrauterine radium in 2 treatments which brought about shrinkage of the uterus and disappearance of the symptoms. The outlook for arrest without hysterectomy seemed hopeful However the finding of residual tumor in the other cases had demonstrated the necessity of hysterectomy wherever possible. Therefore operation was performed in spite of hypertension obesity diabetes advanced age and residuals of pelvic inflammation.

Residual carcinoma was present 75 days after the first radium treatment of 4 500 milligram hours, a dose which is considered adequate by many operators. Five and one half months after the second radium treatment of 4,400 milligram hours several small slands of residual cancer could still be found deep in the myometrium. They might have remained dormant during the rest of the pa

usual preoperative course of radium showing residual zone of carcinoma in only one of the multiple sections taken ×63

tient s life span but their removal increased the possibilities of a cure

CASE 8 Moderately undifferentiated adenocar cinoma early almost completely removed at original biopsy curettage surgical treatment only

This patient aged 30 years white was admitted to the hospital December 4 1944. Menses had customarily lasted 4 days with moderate flow. However she had a prolonged menstrual period lasting 8 days in August and again in November and December 1944. There was no intermenstrual bleed.

The vagina appeared normal the cervix was smooth firm and closed. The corpus was small and free the ovaries normal.

The uterus was curetted thoroughly and a moderate amount of soft grayish tissue was obtained Microscopic examination revealed moder ately undifferentiated adenocarcinoma (Fig. 35). Panhysterectomy and bilateral salpingo-oophore tomy were performed. There was no evidence of extension or metastasis. The uterus tubes and ovaries appeared normal.

The interior of the uterus seemed normal when inspected grossly but on microscopic examination one minute neoplastic focus was found others apparently having been curetted away (Fig 36)

The postoperative course was uneventful 3 months later the patient was well and showed no evidence of disease

This is an early case of moderately un differentiated adenocarcanoma of the uterus treated only by extripation of the uterus tubes and ovaries. The curettage for biopsy almost completely removed the tumor

CASE 9. Moderately differentiated adenocar cinoma corpus uteri, advanced with metastasis to ovaries

This patient, aged 58 years, white was admitted on August 11 1942 with a history of daily bloody spotting from the vagina for many years. Menses ceased at 40 years.

The patient weighed soo pounds. Abdominal palpation revealed large masses rising from the pelvis to the level of the umbilitions. The curva was high in the vagna, smooth and closed. The fundus could not be distinguished from the lower abdominal masses. There was no induration or fixation of the pelvic floor.

At operation the uterus was two and one half times normal size soft and nodular. Both ovaries formed large cystic lobulated tumon, 35 centl meters and o centimeters in diameter. The ovarian tumon fallopan tubes and supracervical portion of the uterus were excised with difficulty.

Microscopic examination revealed extensive infiltrating moderately differentiated adenocarcinoma of the uterus with bilateral ovarian metastases

Sixteen days later radium was inserted into the cervix and vagina for a total dose of 3 600 millipram hours. An incomplete course of postoperative roentgen therapy was given elsewhere. Six months later the patient died with peritional carcinoma tosis sactice and a large metastatic retroperatoreal tumor

This patient is recorded as an instance of ovarian metastasis, the significance of which will be discussed later CARE 10. Adenocarcinoma corpus uteri, il

Became of the term of the patient of the term of the patient of the pat

This case demonstrates the necessity for cophorectomy as part of the routine triat ment of adenocarcinoma of the uters. The use of radium alone is attended by the darger of neglect of oversan metastasis.

#### ANALYSIS OF CASES

In this series of 10 cases of adenocarcinom of the uterus, 9 were moderately advanced of advanced but without induration of the pirk ligaments, and were therefore considered operable. Carcinoma protruded from the cervical os in two uters and ovarian metastas as subsequently found in 3 patients. Microscopic examination revealed moderate differentiation (grade 2) in 4 cases, moderate in-

differentiation (grade 3) in 4 cases, and complete undifferentiation in 2 cases. This distribution is atypical in that most large sense have shown the majority of cases to be differentiated adenocarcinoma.

In 7 of the 10 cases treatment with radium was followed by panhysterectomy and bi lateral salpingo-oophorectomy. The radium dose ranged from 6 030 to 12,480 milligram hours. Case 1 (the only instance of adenocarcinoma of the endocervix) had an x ray tumor dose of 3 030 r followed by 8 000 milligram hours of radium.

The size of the uterus was moderately or greatly reduced following radium. In Case 7 for example the uterine canal shrank in length from 8 to 4.5 centimeters in Case 2 the uterine canal shrank from 12.5 centimeters to 5 centimeters to 5 centimeters.

The operative procedure was not unduly difficult except in Case 7 in which the residuals of pelvic inflammation complicated the operation. In every instance the parametrial tissues were somewhat sclerotic, with lack of resiliency and the sutures had to be tied with care. The uterine vessels seemed smaller than usual. In one instance the uterine veins were torn on each side as the uterius was being elevated. The Richardson conservative panhysterictomy technique was used in all except Case 3 in which a radical dissection was performed on the right side only because of slight preradiation thickening in the right uterosacral ligament.

Interesting was the finding of nests of apparently viable cancer cells in the superficial myometrium in 6 of the 7 excised uteri, with deeper extension in 3. The one uterus (Case 2) in which no residual carcinoma was found had a highly malignant undifferentiated adenocarcinoma which received 12,480 milligram hours of radium given in 2 exposures.

The location of residual carcinoma deep in the myometrium explains why probatory curettage performed several months after radium treatment in order to evaluate its effectiveness, may fail to extract the residual carcinoma.

It is possible that, after irradiation some of this residual carcinoma might not have manilested itself clinically for 5 years or longer However hysterectomy is necessary to complete eradication of the local tumor

Reasons why the combined radium surgical treatment gives the best results according to the literature include (1) reduction of intra uterine infection preoperatively (2) reduction in aize of the uterus simplifying the operative procedure (3) immobilization of cancer cells in the uterus reducing metastasis (4) sclerosing of lymphatics and blood vessels reducing metastasis (5) prevention of recurrence from operative spill in the vagina and abdominal incision and (6) favorable results borne out of statistical evidence

Statistical evidence however is the only concrete information on the value of preoperative radiation. The available statistics discussed previously are based on small series varying from 10 to 37 cases. The 5 year arrests range from Sheffey s 38.4 per cent in 30 cases to Arneson s 90 per cent in 10 cases. Series of as many as 100 cases with uniform radium treatment in doses of 4000 milligram hours or more should be available before the rôle of preoperative irradiation can be evaluated.

Preoperative roentgen therapy has been recommended by some notably Miller who emphasizes the additional destruction of tumor cells in the parametrium by this method. However the intensive x ray therapy necessary to give a lethal tumor dose may cause destructive changes in the bowel, and adhesions The immediate postradium com plications following the use of large doses were not serious. The one instance of acute pelvic cellulitis (Case 7) followed a relatively small radium dose of 4 500 milligram hours. How ever the later deletenous effects of intra uterine radium in the large doses employed in this series are not to be overlooked. Post operative hospitalization is lengthened Recovery of vitality is often delayed for months. There may be delayed healing of the vaginal wound intermittent diarrhea, and frequency of urination If the eventual cure rate is in creased these disadvantages can be disre-

One patient (Case 8) had undifferentiated adenocarcinoma for which many authors recommend preoperative radium. The short

history scant endometrium and small uterus indicated an early lesion. Hysterectomy was performed without preliminary radium. Three natients (Cases 2 o and 10) had metastasis in the ovary This not uncommon incidence of ovarian metastasis is frequently overlooked in planning therapeutic procedures for adenocar cinoma of the uterus. It constitutes an important argument against the use of radium alone in the treatment of this disease. Preoperative radium cannot materially affect the metastatic lexion in the ovary. Consequent postradium hysterectomy should not be unduly delayed.

#### SUMMARY

Ten patients with adenocarcinoma of the uterus were treated in the past 3 years at Walter Reed General Hospital, Seven patients received unusually large doses of таблит (6 010 7 000 7 000 8 000 8 000 10.410 12.480 milligram hours) followed by hysterectomy 28 days to 6 months later. Six of these 7 uten showed residual carcinoma. The one case in which there was no remaining carcinoma after radium was an extensive undifferentiated tumor in a large uterus treated with 12.480 milligram hours radium One nationt with very early undifferentiated adenocarcinoma was treated with surgery alone Three patients had ovarian metastasis.

#### CONCT TWO IN

- This study suggests that radium alone will not completely eradicate adenorationers of the uterus. Subsequent excision of uters tubes, and ovaries is necessary
- 2 The exact role and specific indicators for preoperative radium therapy have not ver been satisfactorily delineated

# PRACTICAL OBSERVATIONS ON THE COPPER SULFATE METHOD FOR DETERMINING THE SPECIFIC GRAVITIES OF WHOLE BLOOD AND SERUM

ERNEST E. MUIRHEAD M.D. Lieutenant M.C. U.S.N.R. M.H. GROW M.D. Lieutenant M.C., U.S.N.R. Dallas, Texas and ALBERT T. WALKER M.D. F.A.C.S. Captain M.C. U.S.N. Washington D.C.

THE clinical significance of the meas urement of the specific gravities of whole blood and plasma or serum has been discussed by Barbour and Ham ilton Weech et al Scudder Kagan Ashworth and Adams (1) Gray and Elhot Phillips et al Technical complications have at times offered impediments to the routine clinical applica tion of several methods particularly in a military sense The authors of the copper sul fate technique (Phillips Van Slyke Dale Emerson Hamilton and Archibald) point out that this is a technically simple quickly con ducted procedure which maintains a sufficient degree of accuracy under the usual variable circumstances to give it much clinical applic ability In the present communication it is proposed to present additional evidence in support of the practical use of the copper sulfate values of whole blood and serum spe dic gravities

#### METHODS

The copper sulfate solutions were prepared as outlined by Phillips and co-workers. The stock solutions (specific gravity 11) were checked periodically by pycnometric procedures. At times when solutions were prepared aboard ship pycnometry was not possible and the fresh standard solutions were checked via a series of normal samples with previously pycnometrically checked solutions. It was possible at other times to compare our solutions with those prepared by Army labor atory facilities ashore. The constancy of checks established much confidence in the technique.

This ork was commenced at the suggestion of and progressed soder the direction of the senior uthor, Fleet Medical Officer Staff Commander Allied N val Forces, Southwest Pacific Area.

Altogether 16 different batches of the stock solution were used in preparing the various standard sets used in the observations

For the actual determination the following procedure was used throughout venous blood was collected in a dry syringe (5 to 20 c c capacity) while stasis was limited as much as possible and drops from the syringe tip be fore clotting occurred were used for measuring the blood specific gravity, the remainder of the blood was allowed to clot in a test tube spun in a centrifuge and the specific gravity of the serum was determined with the aid of a medicine dropper

The Sahli hemoglobin measurements were conducted first with day light then with artificial light as background for color matching 145 grams per cent were considered as 100 per cent normal. The red blood cell counts were done with routine type of equipment 10 squares being counted on each occasion.

#### NORMAL VALUES

The normal series were taken from inactive normal healthy. Army and Navy personnel (males) most of whom had been established in staging areas at sea level in tropical local ities for weeks to months. The samples were taken throughout the day prior to which time the individuals had been ambulatory for varying intervals.

The frequency distribution of the whole blood specific gravity values on 577 different individuals is given in Table I The following features of these data are emphasized. The over all range is 1 o52 to 1 c64 with only one value falling in each of these extremes the arithmetic mean value 1 o58: the standard deviation ( $\sigma$ ) is occip the mean  $\pm 2\sigma$  equals 1 o543 to 1 o619.

The frequency distribution for the serum values on 574 of the above 577 samples is also given in Table I The range for these values is 1024 to 1030 with only one value occurring below 1025 the mean is 10273 the equals 0013 the mean ±20 equals 10247 to

These normal values have been taken as the basis for evaluating values obtained from subjects under various abnormal states in tropical zones (New Guinea to the Philippine Islands). It has been considered safe to state that blood specific gravity values by this technique outside of the range of 10543 to 10519 (mean ±20) are significant in denoting red blood cell dilution or concentration beyond normal limits. By the same token serum specific gravity readings outside of the range 1024 to 10290 have been considered significant in denoting dilution or concentration of the serum proteins beyond normal limits.

FPECIFIC GRAVITY VALUES RED CELL COUNT INEMOGLOBIN CONCENTRATION (SAILL) COMPARISON ON NORMALS

It will be noted in Table II that the Sahli hemoglobin concentration as read against ar tificial light averaged about 0.8 per cent higher figures than the comparisons read against daylight.

All three of these values (specific gravity of blood hemoglobin concentration red blood cell count) depend mainly on the concentration of red cells per unit of blood for their level and so long as the methods of determin ation are reasonably correct one expects a satisfactory correlation between the values. The correlation obtained by the routine measures as demonstrated in Table II seems satisfactor ily close and resembles similar correlations presented by Ashworth and Adams (1) and by Grav and Elliot utilizing other specific gravity and hemoglobin methods.

VARIATIONS IN SPECIFIC GRAVITY VALUES IN MORMAL SUBJECTS INDUCED BY VALUES SOLUTIONS ADMINISTERED INTRACEMENTAL

The variations in the specific gravities of subjects over a 24 hour period effected by setsantial volumes of physiologic saline solution, normal human plasma, concentrated human plasma (four fold concentration) and coordinated human albumin (25 grams per cert) given intravenously sere observed. The results are presented in Figure 1 which also contains similar observations following a comparable volume of whole blood given 2 subject

with slight hemodilution Considering that the specific gravity of whole blood is due mainly to the concentra tion of red cells and that the serum species gravity is due mainly to the concentration of the proteins, certain observations are ende Saline, normal plasma, concentrated place and concentrated albumin all gave ree to dil tion of the recipients red cells. Following the latter three solutions this dilution remares evident until 12 to 24 hours had passed whe preinfusion levels were reached. For 12 .22 the dilution was evanescent and a premiuse level was noted 90 minutes after the infu-The protein-containing solutions (normal platma concentrated plasma, concentrated a

bumin) produced little change in the serum protein concentration. Conversely saline effected a marked drop in the protein concentration which returned to preinfusion levels only after some 6 hours had elapsed. Blood given to a subject with specific gravity values highly below normal caused an elevation in the red cell concentration the continuation of which must have become augmented by red cell production and liberation from active bone marrow areas. Little change occurred in the serum protein concentration from this in fused volume of blood.

ISOLATED CASES ILLUSTRATING THE CLINICAL APPLICATION OF COPPER SULFATE SPECIFIC GRAVITY VALUES

The isolated cases used in demonstrating the clinical application of the specific gravity values were all battle casualties occurring in various engagements during the recent Philippine campaign. At present the emphasis is placed mainly on the specific gravity studies as they deviate from the normal. A correlation of such studies with other aspects of casualty care, as types and volume of intravenous solutions used, types of cases response to therapy—with main consideration of the shock state—will be presented later in a compilation of over 300 closely observed cases out of some 5000 casualties handled by our medical facility (16)

#### HEMORRHAGE

It has long been emphasized that the loss of whole blood from the circulation is followed by dlutlon of the remaining red cells. Whether there is dilution of the scrum (or plasma) pro-

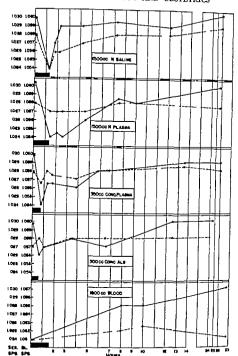

Fig. 1. A demonstration of the changes in the specific gravities of whole blood and serums induced on normal subjects by various commonly said intervence indust. Conparable volumes were used. The normal plasma, concentrated plasma, concentrated albumin solution each contained approximately 75 grams of proteins. The blood was diluted about 1 to 5 with clitera-destrose authoroughust preservative solution. The time interval for the infusion is designated at the lower left corner. The solid finepresent whole blood specific gravities, the broken lines serum specific gravities.

teins over a sustained period seems to depend on several factors as the extent of blood loss, the interval of time before a determination is

made, the state of the protein stores, the demands on the protein stores by other complications, etc. The hemodilution commerces

early but when compensation by the subjects own resources is all that induces it the final degree of dilution of the blood may not occur for 24 to 36 hours (7) During the first hour the dilution may not exceed 10 per cent (13) indeed in occasional patients with hemor rhagic hypotension it has been reported that there may be no dilution or actual concentration of the red cells (hemoconcentration) (6 The administration of intravenous fluid not containing red cells particularly protein fluids as plasma or albumin solutions by their inherent properties accelerates the devel opment of the final degree of hemodilution in hemorrhage cases (17)

The extent of the drop in blood specific gravity the effect on the serum specific grav ity the state of the blood pressure, the clin ical picture, the response to therapy (including the quantity and quality of the fluids used) are all important in estimating a case of acute blood loss clinically Examples demonstrating the value of specific gravity studies will be divided into the patient (1) suspected of hav ing a substantial hemorrhage (2) with hemor rhage with embarrassment to the circulation and (3) with hemorrhage followed by volume compensation (acute hemorrhagic anemia)

Following is an instance of a patient suspected of having a substantial hemorrhage

CASE 1 This patient sustained multiple lacers tions involving the skin and muscles of the upper ex-

tremities back and legs there was no fracture. He was seen about 4 hours after the injury ago cubic centimeters of normal plasma had been given in travenously. The specific gravity values were 1 054 for blood 1 0265 for serum, the blood pressure was 120-80 millimeters hemoglobin, the pulse rate was 100 beats per minute, but the patient was restless confused the pulse was weak. Following 1 000 cubic centimeters of normal plasma by vein there was obvious clinical improvement and 75 hours later the specific gravity figures were 1 050 and 1 026 After 22 to 23 hours the specific gravities levelled off at 1 051 to 1 027 slightly lower than the normal range for the blood value.

The patient sustained injuries conducive to blood loss the extent of which was unknown. The clinical improvement with plasma alone plus a stabilization of the blood specific grav ity at levels only slightly below normal indi cated a blood loss not of extreme proportions. Without the concentration studies complete confidence in this case would have been more difficult.

Hemorrhage with moderate to severe circula tory embarrassment. We are considering here the patient with tendency toward a lowered arterial pressure weak pulse restlessness or disorientation to coma lowered urinary out put, paleness with or without sweating etc. following types of injury conducive to copious hemorrhages Some have termed the state hemorrhagic shock (5) others prefer hemor rhagic hypotension applied to recoverable cases (22) while others object to applying the terms shock where simple hemorrhage appears to be the main complication (14) The demonstration of hemodilution by the copper sulfate method is our main concern at present.

CASE 2 The first patient sustained severe injuries to the right leg following an attack on one of our ships. He was seen some 8 hours later at which time there were clinical indications of severe circulatory embarramment pulse too weak to be definitely pal pable, semicoma, marked pallor lowered skin tem perature. The right leg was severely crushed and mangled and it was learned that the individual had been in the water (sea) some 45 minutes without a tourniquet before being rescued. Table III demon strates marked hemodilution Following the admin istration of concentrated albumin and whole blood (amount in table) there was much improvement, the right leg was amputated, additional blood and plasma were given and later the specific gravity of blood was only slightly below the normal range. The patient did well subsequently

CARLY The second patient was seen 3 to 4 hours following the injuries, extensive shrapped lacerations of the face, right arm, and right leg. The patient was weak, pale, cold the pulse quite weak, the blood pressure 10x/68 After 1 too cubic centimeters of whole blood there was much improvement but a total of x,800 cubic centimeters of blood was required to elevate both blood and serum specific gravity values to near the normal ranges (Table IV). The patient improved and progressed nikely

Hemorrhage with acuts posthemorrhagic anemia This group includes the patients seen 2 to 3 days or longer following injuries producing blood loss and the final degree of hemodillution has been reached At this time it is considered that an insufficient interval has elapsed in many cases for dictury and bone marrow depressing complications to affect the blood picture appreciably

Case 4. The first illustrative patient (Table V) was seen 2 days following the injury (gunshot wound

with abdominal perforation, injury to left kidney and apleon, emergency splencetomy). The dilution of the red cells was prominent and it required 3 750 cake centimeters of whole blood given in 48 hours time to clevate the specific gravity to normal levels.

Case of the according to the Well Brivier can day following the bijury by their largement casing laceration of the abdominal wall and perfocus, or foration of the abdominal wall and perfocus, or foration of the minary badder and rectum. On this occasion, there was dilution of both red chius serum proteins (Table VI). The specific parity values returned to normal range following 4400 cubble centimeters of blood.

#### DITTO NO

Early phase Here is included burn assessen while there is increased permeability of capillaries giving rue to a decrease in the plasma volume and hemoconcentration (shock period)

CARE 6 The first patient was seen 8 hour following the hum (Table VII). He had recrived plans intravenously prior to this time but the amount was not known. When seen there was proconnect centration of the red cells as demonstrated by a blood specific gravity value well showe the normal range. The extent of capillary damage and plans volume depletion can be appreciated by the volume depletion can be appreciated by the volume of protein solution required to lower the blood specific gravity to normal levels.

Care 7 fine second case is presented mainly because it reveals the highest blood specific parity values seen. This patient came under our observation 4 hours after severe burns involving the entire body surface with the exception of about so per set of the left arm and the area covered by symmotor trunks. The left fey was parched, the foot has at cold. The patient was in deep abock, accommode the pulse not palpable, the aith about the grain cold and prominent with bluish-gray moting the first blood samples (from femoral velin) were a ceedingly thick and almost black in color (species).

gravity 1,074) The tremendous quantities of albu min and plasma required to control the hemoconcen tration are given in Table VIII The blood specific gravity returned to normal levels, the left foot be came warm and pink, the patient regained con sciousness. At no time was there evidence of pulmon ary edems or right sided cardiac embarrassment (no venous engorgement) The first urine specimen con tained four plus albumin red cells and casts As soon as consciousness began to appear troublesome retching with vomiting of blood began. The patient was reported to have died later aboard the evacuating ship (With the patient so severely burned and without treatment for so long and in such extreme shock, it was decided to cope with the hemoconcen tration regardless of the volumes needed so long as venous congestion or pulmonery edema did not be come evident, as this approach seemed to give him his best chance)

Later phase This group includes burn cases seen after 72 hours when anemia and hypoproteinemia begin to be prominent.

Case 8 This patient had sustained burns involv ing about 40 per cent of the body surface of second and third degree types 5 days before. Plasma had been administered the amount was not known. On admission the blood-serum specific gravities were 1 047 to 1 019 Following 300 cubic centimeters of concentrated albumin solution (75 grams albumin) 500 cubic centimeters of normal plasma and 1 100 cubic centimeters of citrated blood during the first day the specific gravity values became 1045 to 1.0215. An additional 1 100 cubic centimeters of citrated blood were given and progress was being made in correcting the anemia hypoprotememia complications when the nationt was transferred for evacuation.

#### ANEMIA

An opportunity for the observation of specutic gravity values in the anemia of malnutra tion was afforded by a comparison of findings in a group of lavanese held by the Japanese as prisoners and utilized as laborers in Noemfoor

Associats of planta, gives were too small to effect algoriticant changes in several protein levels.

the same location the Japanese were robust and well fed. In the captives the specific gravity values were indicative of severe anemia and hypoproteinemia while in the Japanese captors the values were within the nor mal range. A correlation with the Sahli hemoglobin values was also obtained Blood and plasma infusions were given to some of these patients but the amounts were too small to alter appreciably the specific gravity values.

The treatment of anemia is demonstrated in a patient with malaria

CASE of This person had not felt well for weeks and had been very Ill for about 10 days prior to ad mission. An extraordinarily heavy infestation with plasmodium falciparum was noted on thick and thin blood amears. The patient was comatose and displayed a dry tongue and some loss of skin turgor The dietary intake had been poor The specific gravities (blood and serum) were 1 041 to 1 021 in dicative of prominent anemia and hypoproteinemia. Following 1 000 cubic centimeters t per cent der trose in saline, 1,000 cubic centimeters normal plasms roop cubic centimeters citrated blood (1) c hours after admission) the specific gravity figures were 1.047 to 1 023 An additional 2 200 cubic centimeters of citrated blood and 1,000 cubic centimeters of normal plasma were given (so s hours after admission) and 16 hours later the specific gravitles were 1.050 to 1.025. At 59 hours the values were 1.051 to 1.0245. The patient improved markedly. The transfusions seemed to be a definite adjuvant to the quinine and atabrine therapy in this case

#### DETIVIDENTION

If one considers that the clinical signs of dehydration (extracellular type with or with out intracellular dehydration) are reliable then serious grades of dehydration have not been encountered as frequently in the wound ed who have access to water as was expected. The clinical signs used include the urinary output and the specific gravity of the urine dryness of the mouth and skin thirst as ex pressed by the patient, loss of skin turgor and elevation of the specific gravity values of blood and serum. Of course the majority of the patients seen had sustained wounds of the extremities with or without fractures and could and would take sufficient water by mouth. Abdominal cases (intestinal perfor ation obstruction colostomy fistula cases) naturally presented more of a strict water

salt balance problem. One such case is pre-

CASE 10. This patient was seen 13 to 14 been idlowing the injury, shrapnel perfection of the siddomen. Alongs bowel and the surface of the wisary bladders are perfectly the bladder required ast at loss had been performed to the bladder required ast the loop of intention brought to the surface (ast supullized). The loop had broken down and probert A firthia.

On admission the patient exhibited signs of sever circulatory embarrassment (shock) come with reriods of restlessness, pulse very weak, blood pressure 00/60 millimeters bemoglobin, palenes, sirit sweating veins inconspicuous. The specific gravity values (blood-serum) were 1.008 to 1.0270, white the normal range. The shock was treated with dtrated blood (2,600 c.c.) and normal saline (1.000 c.c.) by vein. There was definite clinical improvement, consciousness was regained, the blood pressure reached 100/72, the pulse was strong and regular bat the nationt had a rayonnus thirst. There was lost of akin turror and the urinary output was periode At this time (7 hours after admission) the medic gravity figures were 1.06; to 1.038, an elevation of the blood value, which indicated a moderate com tration. One liter of a per cent dextrose in salme and aco cubic centimeters of normal plasma lowered the specific gravity value of blood to 1.053 (10 hours at ter admission) but it returned to an elevated value (1.061 to 1 028 by 37 hours after admission) At this time 2,000 cubic centimeters of dextrose salise and 500 cubic centimeters of normal plasma were gives and the values again dropped to 1 osy to Loris at 41 hours After an additional 500 cubic centimeters of normal plasma the values were 1.051 to 1.025. The patient was much improved, quiet but continued to ask for large quantities of water The bowd costs ued to discharge coplous quantities of fluid Addtional saline and plasma (2,000 c.c. and 500 cc.) were given to replace that lost through the assaure opening. After transfer this patient was reported to have done well.

Intravenous protein feeding When plasma solutions are administered by vein largely for the dietary value of the contained proteins, specific gravity values may be of use. Should the patient be receiving 1,000 to 2,000 cubic centimeters of normal plasma daily (60 to 100 grams proteins) and no significant alterators are noted in the concentration values from dry to day then one has a good idea that the similatered solids and fluids are being utilized. A case in point was a patient with acute caterihal jaundice and initial specific gravity values of 1 o52 to 1 o23. Eleven and one-hill hours after 1 250 cubic centumeters of normal

plasma were given the values were 1 050 to 1.0255 An additional 1 250 cubic centimeters of normal plasma were given and later the specific gravities were 1 052 to 1 027

#### EVALUATION OF STUDY

This study was begun by establishing nor mal values of whole venous blood and serum specific gravities for males of military age at sea level in a tropical climate. Then the ranges means and standard deviations were obtained. Significance was given to values out side of the range obtained by the mean  $\pm 2\sigma$ 

A comparison of the blood specific gravity values, the hemoglobin concentration as measured by Sahli's method and the red blood cell count gave a correlation similar to that obtained by Ashworth and Adams (1) Altera tions in the specific gravity values as produced by various solutions given by vein gave results similar to results in other studies (2 9 10 11)

Illustrations of the copper sulfate procedure as applied to the care of various types of abnormalities seen in battle casualties were pre sented. These concentration studies (specific gravity of blood and serum) were of great value in demonstrating trends in the make up of the circulating blood (hemodilution hemoconcentration anemia hypoproteinemia etc.) and to a great extent in demonstrating the seventy of trends. In conjunction with the clin ical picture (history physical examination etc.) the blood pressure level and the response to therapy they formed a valuable asset in the appraisal and therapy of the wounded.

#### CONCLUSION

The copper sulfate method for determining the specific gravities of blood and serum can be used to great advantage in the appraisal and treatment of various surgical conditions Additional evidence supporting this concluaion has been presented. The method is of par

ticular value in military use when several factors as the sudden arrival of large numbers of wounded men the necessity of rapid decisions concerning the shock state the appraisal of patients before anesthesia and operative procedures are instituted the need for medical judgment during attacks by the enemy make its simplicity speed, degree of accuracy and instant applicability most desirous

### LUMBAR APPENDICITIS AND LUMBAR APPENDECTOMY

W WAYNE BABCOCK, M.D., F.A.C.S., Philadelphia, Pennsylvania

SOMEWHAT rare form of appendi citis which may be mistaken for other conditions unless the symptoms are definitely understood, has not, to my present knowledge been clearly described It is a type in which the appendix is posterior and lies against the peritoneum dorsal to or below the cecum The general peritoneal cavity is not involved and the characteristic abdominal symptoms of appendicitis are absent. Without gross perfora tion and usually without intra abdominal pus formation, bacteria from the appendix penetrate the thin peritoneal layer and spread in the loose extraperitoneal connective tissue of the loin and pelvis, producing first a watery edema like that often seen in the deep tissues of the anterior abdominal wall from appendi citis, but with a much greater tendency to a spreading purulent, and necrotic process. The tela subserosa or extraperitoneal con nective tissue of the posterior abdominal wall and pelvis is much more abundant is looser contains more fat, and is less resistant to in fection than that of the anterior abdominal wall. There results from the lower involvement of the right extraperatoneal space a pelvic abscess, and from the upper type a right perinephritic abscess. Coincidentally inflammatory products within the appendix usually discharge into the cecum and the appendix undergoes resolution.

I have long believed that appendicits without intra-abdomial suppuration is a common cause of the so-called kitopathic perinphritic abscess. This concept, however apparently has received little attention from urologists, although Hugh Young mentions appendiceal abscess as a possible cause of

perinephritic abscess.

If an anterior abdominal incision is made in the early stages of lumbar appendicits with removal of the appendix, the operator may encounter nothing to direct his attention to

From the Surgical Service of Temple University Hospital, Philadelphia.

the retroperstoneal inflammation. The pertoneum over the lumbar area is not necrotic or perforated and in the limited area not correct by the cecum, shows no greater inflammators change than that usually found continues to an inflamed appendix. If careful pairates were made a cushion-like elevation of the peritoneum dorsal to the appendix might be detected but I dare say few operators have considered such examination necessary With the lower type a large extrapertiment pelve abscess which later forms may be mistaken for and drained as a localized intropertunal collection Likewise the operator will over look the primary appendicitis when without opening the peritoneum, he drains only the secondary retroperitoneal or perinephnic Apparently the septic extension abscess. through the pentoneum is uncommon if the appendicitis leads to a plastic or purulent perstoneal exudate. In other words, the extraperatoneal extension rarely is associated with a gangrenous or perforated appendix

The signs and symptoms of the lower type of lumbar appendicitis are striking and, when fully developed very characteristic. The attack may start, as in the usual case of sppendicitis with epigastric distress, names, moderate fever elevation of the pulse rate, and polymorphonuclear leucocytom. The pain tenderness, and rigidity however de not localize at McBurney a point but rather in the right lumbar muscles above the crest of the ilium. Medial to the right anterior smer ior spine of the ilium the signs of appendicts, such as local tenderness, muscular rigidity and the Iliopsoas and obturator tests, may be entirely absent The patient however may complain of pain and tenderness over the anterior surface of the right thigh, of the right scrotum or in the female of the right lablum majus. In the inflamed extraped toneal connective tissue back of the cecum le the genitofemoral nerve, the external sperms tic branch of which innervates the cremester and scrotel or labial skin, and the himbounguinal branch, supplying the skin of the upper anterior thigh. From involvement of the lateral femoral cutaneous and the femoral and obturator nerves symptoms referred to the lateral surface of the thigh, lower anterior surface or medial surface of the thigh, or knee also, may be produced. As the ureter runs through the intensely inflamed connective tissue, ureteral colic and hematuria may be present. The characteristic syndrome of lumbar appendicitis is lumbar pain tender ness and muscular tension associated with pain in the anterior right thigh, testicle or labium to which may be added vesical irrita bility and hematuria A degree of lumbar scoliosis with concavity to the right may develop and later from the inflammatory exudate, the margins of the right psoas muscle may appear blurred or the muscle shadow obliterated on roentgen examination

The pathological changes can be appreciated only by an incision exposing the extraperatoreal connective tusue in the right lumbar and iliac regions together with the

appendix.

In operating an oblique incision is made above the creat of the right ilium along the fibers of the external oblique which are separ ated and partly divided. The retropentoneal connective tissue space is entered and evacuated of the inflammatory exudate and wiped dry The peritoneum is opened by a small incision behind or below the cecum through which the appendix is delivered. The mesoappendix is clamped and divided in sections and the base of the appendix doubly ligated and divided by a cautery between the clamps and beyond the ligatures The mesoappendix is ligated over the stump of appendix in sec tions with one of the ligatures. As a rule the opening in the peritoneum may be closed with 36 gauge alloy steel wire and the septic retroperitoneal space drained the wound being closed about the drain with layer sutures of No 32 wire The retrocecal appendix hes against the peritoneum and is accessible from

The following is the report of a typical case of lumbar appendicitis

Mr H B 22 years of age a medical student be came III in the afternoon with generalized dull aching abdominal pain after eating Chinese food At 6 o clock the following morning he had a severe chill was nauseated and vomited and at 10200 a.m. he entered the accident dispensary of Temple Uni versity Hospital with the diagnosis of a right unnary tract calculus as it was thought that the urine contained blood. At this time the hemoglobin was 13 5 (79 9 per cent) erythrocytes 5 030 000 color index leucocytes 13,800 polymorphonucleurs 82 lymphocytes 13 monocytes 3 eosinophiles 1 nonfilaments 51, filaments 31 urine clear, no sediment, acid, cloud of albumin much amorphous material, blood urea nitrogen 45 milligrams plasma carbon dioxide o so The abdominal ache disappeared and there were several diarrheal movements. A month previously he had had a transient acute abdominal attack with names, vomiting and constipation )

In the afternoon he was transferred from the accident dispensary to the hospital with the impression that he had an acute gastroduodenitis and possible stone in the right kidney or ureter. His temperature then was 1033 pulse 86 respiration 22 leucocytes 26 000 polymorphonucles rs 80 non filaments 78 filaments 11 blood ures nitrogen 60 milligrams, urine 1028 no casts or blood cells

occasional leucocytes

The patient a well developed and heavily muscled young man was seen in consultation about 4:00 p.m. He then was complaining of pain and sensi tiveness in the lower right loin the anterior right thigh and in the right testicle. There was no abdominal distention muscle resistance or tenderness Posterior to the line of the right anterior iliac spine and above the crest of the right illium was a painful area with marked tenderness and increased muscular tension. With a diagnosis of retrocecul appendicitis. and secondary lumbar phlegmon operation was per

formed about 4 30 that afternoon, An oblique o centimeter skin incision was made about 2 centimeters above the right flux crest. The fibers of the external oblique muscle were separated and the lumbar fascia and subpentoneal connective tissue (which were greenish seminecrotic, mal odorous, and contained 60 to 00 c.c. of pus) were exposed. The area was mopped out and a 3 centimeter incision made through the peritoneum under the cecum exposing the appendix, which was swollen, injected and very lightly attached to the peritoneum but without perforation or plastic exu date. The peritoneal surface was moist from a very small amount of turbid odorless fluid. The base of the appendix was doubly ligated with No 32 alloy steel wire, divided by cautery the mesosppendix ligated over the stump with one of the ligatures, and the peritoneal opening closed with fine wire autures. The wound was lightly united with interrupted were sutures around a drain extending extraperitoneally from the pelvis

Pathologic report. The appendix measured 5 by 1 centimeter and was not perforated. The serosa was thickened and injected, the lumen narrowed but not obliterated. The mucosa was infiltrated by plasmocytes lymphocytes, eosinophiles and neutrophiles, the epithelium lacking in many places and the glands replaced by fibrous connective tissue con taining inflammatory cells. The picture was that of a healing acute appendicitis with evidence of a previous inflammatory attack. The day following operation the urine contained a few red cells and leucocytes.

The patient had an uninterrupted recovery and was discharged from the hospital 15 days after the operation.

#### BUMMARY

A type of appendicitis is described in which the inflamed organ has a posterior or retrocecal position, and from which the infection spreads through the thin contiguous peritoneal layer with little abdominal reaction and produces a spreading phlegmon or abscess in the poorly resisting loose areolar tissue of the retroperitoneal space in the right lumbar and pelvic areas. As the signs and symptoms are predominantly in the right lumbar region, I have termed the condition 'lumbar appendi The appendicitis tends to subside spontaneously probably largely by discharge of inflammatory products through the open lumen of the appendix into the cecum and is associated with so few characteristic symptoms as to be overshadowed in the later development of a pennephritic or pelvic abscess. In those cases in which the appendi ceal symptoms are more definite the retro-

peritoneal extension may be diagnosed and

drained through the abdomen as a localized intraperatoreal collection.

The initial symptoms of lumbar appendicitis usually are abdominal colic, names and fever soon followed by pain, tenderness and muscular rigidity in the loin, but with a degree of fever and possibly a chill unusual in scute appendicates. This condition is to be at tributed to the greater toxic absorption from the retroperatoneal space than from the peritoneum. Especially characteristic are symptoms due to the irritation of structures surrounded by the inflamed extraperitonal connective tissue, as the right genitofemoral, lateral femoral cutaneous, femoral and obtuntor nerves and the ureter. The syndrome of Dain, tenderness, and rigidity in the lower right loin with pain and tenderness referred to the right testicle and anterior part of the next thigh, occurring after a brief abdominal at tack, is quite diagnostic. In treatment it is important that the

appendix be removed and the phlegmon drained through a lumbar or retroperitored approach otherwise the surgeon may remove an inflamed appendix and overlook the retroperitoneal phlegmon, or drain the pelvic or perirenal abscess and overlook the appendix With removal of the appendix the peritoneum may be closed, or drained with the lumbar pelvic space through a single lumbar increon.

# CORRECTION OF BLOOD LOSS DURING SURGICAL OPERATIONS

CLARENCE E. CROOK, M.D. VIVIAN IOB Ph.D. FREDERICK A. COLLER M.D. F.A.C.S.
Ann Arbor Michigan

THE study of blood changes produced by hemorrhage has received much attention in the past. Considerably less is known about the changes produced in the circulating blood by various types of anesthesia, the intravenous injection of fluids and the various exigencies of major surgical operations. These variables are so numerous that systemic consequences of trau matizing operations are not reflected in the circulating blood and the determinations of hematocrit, hemoglobin or plasma proteins give little information as to the quantity of blood lost or of pending shock Support for this statement is found in a brief review of the hterature and in the analysis of the blood changes of 35 patients undergoing major sur gical operations to be presented

Dyson, Plaut, and Vaughan observed the reactions to changes in the blood volume resulting from the removal of 540 millihters of blood from 8 healthy donors in whom many of the variables were reduced to a minimum They noted that in only one instance the change in blood volume as determined by the dye method was found to correspond to the calculated value. In the others dilution or overdilution was associated with an increase in mean corpuscular volume suggesting that some of the fluid replacing the blood lost was absorbed by the red cells. The authors also point out that blood loss may occur without affecting the hemoglobin level

A rarely considered variable in the normal individual undergoing blood loss is the uncer tain amount of blood expressed from the spleen. According to Lewis, Werle, and Wig gers, the spleen contracts vigorously during hemorrhage, and may shrink to a volume of 50 per cent or less of its original size. Wu in

1943 found the capacity of 20 spicens to vary from 60 to 400 milliliters, a volume which may be added to the blood volume during hemor rhage

Thus it is evident that, even in simple un complicated hemorrhage in relatively normal individuals variable factors contribute to make changes in hemoglobin plasma proteins, and hematocrit unpredictable. To these factors must be added the inherent differences present in each surgically sick patient and the various methods used in treatment. In general, surgical operations anesthesia shock varying degrees of dehydration and malnutrition fever anemia hypoproteinemia, and in travenous infusions of crystalloids plasma and variable whole blood all contribute to changes in the circulating blood.

Windfeld, in 1937 made direct measure ments of blood lost during operations and demonstrated that determinations of hemoglobin concentrations before and after operation failed to give quantitative information regarding the amount of blood lost.

Stewart and Rourke, recording the changes in the volumes of blood and interstital fluid during operations under ether anesthesia, stressed the fallacy of assuming a quantitative relationship between changes in concentration of hemoglobin or plasma proteins and changes in plasma volume. From their observations reduction in plasma volume may be greater than can be accounted for by hemorrhage.

Ariel, Pack, and Rhoads compared liver blopsy specimens secured at the beginning and the end of gastric operations and found that hepatic cells usually swell during surgery. The average increase in total liver water was 1 I per cent. By inference, the red blood cells also may take up some of the fluid transferred from the interstitial space to the blood stream.

In March 1945 Evans published conclusions resulting from the recent studies of three

Aided by Grant from the Horace H. Rackham Fund. From the Department of Surgery University of Michigan Medical School, Ann Arbor Michigan.

separate shock research groups (of New York, of Atlanta, and of Richmond) in which estima tions of blood volume were made by means of the dve method. He presented simple reasons why the determination of hemoglobin and plasma proteins does not suffice in estimating the blood volume in surgical patients. He pointed out that 'in whole blood loss almost equal quantities of red cells and of plasma are missing so that hemoglobin and plasms protein concentrations will be relatively unchanged and the surgeon is given a false sense of security In situations when moderate quantities of red blood cells and much plasma are lost, there will be hemoconcentration yet there is no indication of red cell loss. Only in situations of relatively simple plasma loss (such as peritonitis and some burns) will hemoglobin and hematocrit give an accurate picture of the trend of blood volume alter ations.

Introduction of intravenous fluids further compilicates the picture. Although Bogert, Underhill, and Mendel found, in 1916 that the blood volume of rabbits injected intravenously with saline returned to normal 30 minutes after the injection later investigations have shown that alterations in blood volume following intravenous infusions last

much longer Gilligan, Altschule, and Volt found that the blood volume increases after intravenous fluids may not return to the nor mal level for 2 hours.

The blood at the end of operation is this resultant of these variable influences, and it becomes impossible to select any one cherical determination indicative of the condition of the postoperative patient, unless it is the determination of the plasma volume, a labor ious and often unsatisfactory procedure in the seriously III patient.

In support of this statement, the data compiled from the determinations of hematomit, hemoglobin and plasma proteins of 35 pa tients before and after major surgical oper ations are presented in Tables I through VI. In each instance the preoperative value is recorded and below it the percentile change from the preoperative value obtained at the end of operation. The blood lost at operation was determined and has been reported eswhere (4) Heparinized blood was used, and a 2 millillter sample sufficed for the 3 deter minations. Hematocrit was measured in sealed, capillary tubes spun until no further change in cell volume occurred. Hemoglobia was analyzed as oxyhemoglobin by the photoelectric method of Evelyn on 20 cubic mili-

neters of well mixed blood measured in the falling drop pipet with the aid of a Guthre pipet holder. This procedure was adopted to avoid the maccuracies of the 20 cubic millimeter blood pipet. Plasma proteins were determined by the method of Barbour and Hamilton and by the use of Weech's formula. Hemolyzed plasmas were corrected for hemoglobin by an adaptation of Evelyn's method before the plasma proteins were calculated from the plasma specific gravity.

Table I is concerned with the changes occur ring during thyroidectomies. In this group only 1 patient received no intravenous fluid. This patient (3) lost 227 milliliters of blood or 7.5 per cent of his total blood volume. A comparison of the percentile changes of both hematocrit and hemoglobin (-10 1 per cent and -10 3 per cent, respectively) and the calculated blood loss (7.5 per cent) indicates an overdilution, similar to the reaction of healthy donors to the withdrawal of blood.

All the other patients in Table I received 5 per cent glucose intravenously during the operation. Patient 10 with a blood loss of 204 millihers or 5 3 per cent showed little or no tendency to hemodilution above that of the blood lost, in spite of 1000 millihers of glucose infused during the operation. In other words, approximately 750 milliheters of fluid have left the blood stream during the operation.

Treal blood volume was calculated from the verage values deter stied by Gebran and Evan, 77 5 multifliers per informs of body wright is the mais and 60 millibiters per kilogram in the female In contrast, patient 15 showed changes in hematocrit (-5 9 per cent) comparable to the blood loss (-6 0 per cent) but both hemoglobin and plasma proteins remained unchanged This instance suggests an absence of hemodilution and even a shrinkage of the red cells

Patient 16 was operated on for a very large tone gotter. In spite of the large blood loss of 725 milliliters, 28 per cent of the total blood volume and the infusion of 1000 milliliters of glucose there was no evidence of hemodilution. Later patient 16b during the second stage of the hemithyroidectomy showed a similar reaction. These findings suggest the rapid disappearance of the intravenous fluid and the absence of hemodilution after large losses of blood.

Table II presents the results of studies during radical mastectomies. Patient 1 received room milhiters of glucose during the operation which involved a blood loss of 821 millifliters or 12.8 per cent of the total blood volume She developed mild hypotension. The per centile change in hemoglobin (-15 3 per cent) corresponded to the blood loss (-12 8 per cent). The hematocnt change (-2 3 per cent) is rather indicative of increase in mean cornuscular volume.

In patient 29 with a loss of 14 6 per cent of the total blood volume, the change in hemoglobin (-18 9 per cent) and in plasma proteins (-17 3 per cent) corresponds to the blood loss with a tendency toward overdilution while

the hematocrit (-11 1 per cent) is indicative of cellular swelling

In these mastectomes the changes in hemoglobin compared more closely with the blood loss than did the changes in hematocrit or plasma proteins. However even the hemoglobin changes are often misleading Blood losses were large averaging 800 milliliters and hypotension occurred frequently

Patients undergoing combined abdominoperineal resection for carcinoma of the rectum are represented in Table III Here the average changes in bematocrit (-5 1 per cent) hemoglobin (-8 0 per cent) and plasma proteins (-6 6 per cent) correspond faulty well with average blood loss (-3 2 per cent) but suggest a tendency toward overdilution. Individually this ideal correlation exists in only one in stance, patient 30. The other cases show con suderable variation. For example patient 7 sustained a blood loss of £83 milliliters (4.1 per cent) of the total blood volume. This patient's reaction to the small loss of blood was a charge in hematocrit of +10.7 per cent, in hematocrit of +10.7 per cent, in hemoglobin of -17 for per cent and in plasma proteins of -1 x per cent. A fairly pronounced hypotension may have been responsible for none of these shifts.

Difficult and prolonged surgery for dissess of the bilinary tract provided the case in Table IV. In these patients hypotension is frequently a prominent part of the surgical picture. In spite of the eristing marked hypotension patient 18 presents blood change comparable to the hemodilution resulting from a blood loss of 8 per cent. On the other hand patient 21 after a corrected blood has of 14.4 per cent (total loss less transfused during operation) showed a hematoric change of -4 5 per cent, and a plasma protein change of -11 i per cent.

May replacement of blood during the operation.

Vitrous oxide, oxygen and other

As mentioned before Pack and associates (1) demonstrated swelling of liver cells in na tients following operation on the stomach. The cases presented in Table V show evidence of swelling of red blood cells as shown by the increased hemotocrit

Table VI summarizes the average blood losses and the average changes in hematocrit. hemoglobin and plasma proteins. losses calculated from the changes in hematocrit, hemoglobin, or plasma proteins would lead to an underestimation of the need for replacement in mastectomies thyroidectomies, biliary tract surgery, and pastric lesions. In combined abdominoperineal resections, the individual estimates would also be uncertain in spite of the fact that the average values shown in the series correspond fairly well to the blood lost.

#### COMMENT

Thus, an analysis of the findings in the 35 cases here presented furnishes further evidence that no easy practicable laboratory procedure will indicate the status of the circulat ing blood in the postoperative patient.

Studies of blood loss invariably show that the loss is almost always greater than the surgeon estimates. It is becoming widely recognized that the only wholly suitable replacement for operative blood loss is whole blood and that the greatest benefits result when the blood is given as the loss occurs.

The surgeon therefore, should plan in ad vance for the adequate replacement of the deficiency caused by bleeding during the oper ation. To do this, he must usually rely upon his own knowledge of the amount of blood loss to be expected in each case. Recognizing this fact the present authors, in a previous publi

cation (a) tabulated the average blood losses occurring during the usual types of operation as calculated from 626 cases reported in the literature

#### CONCT HETONE

Whole blood is required adequately to replace blood lost during surgical operation The replacement is most effective when whole blood is given as the loss occurs.

The amount of blood needed in each err gical case can seldom be determined directly Hemoglobin hematocrit, and plasma protein concentrations fail as an accurate measure of this need. Plasma volume determinations are more accurate, but are too labonous and time consuming for routine use

A knowledge of blood loss during operation as available in the literature offers a practical basis for planned transfersions during oper etion.

#### PATELLECTOMY IN THE MILITARY SERVICE

#### A Report of 19 Cases

THOMAS HORWITZ, M D F.A.C.S Lieutenant Colonel M C A U S Philadelphia Pennsylvania, and R. G LAMBERT Captain M C. A.U.S San Francisco California

HE subject of patellectomy or complete excision of the patella has long been a controversial one. Those opposing the procedure argue that if the patient regains complete flexion of the knee there is resulting limitation of extension and conversely if he has complete extension he cannot fully flex the knee (Fig. 1a b)

We believe that patellectomy can be a very successful operation and that patients with complete patellectomy can have normal knee function. Many operations have been devised for this procedure each claiming some special advantage. We carry no banner for any particular operation, but believe only that the essential aim should be to eliminate the slack in the quadriceps tendon which is created when the patella is removed.

The amount of slack to be eliminated has not been adequately defined in the literature Consequently we have herein attempted to clarify the subject on a mathematical basis, although realizing that the figures used are averages and do not apply to any given case For purposes of the computations we have accepted 2 centimeters as the average thick

Presented at the meeting of the Chicago Orthopedic Society April 3, 945, at V ughan General Hospital, Hines, Illinois. ness and 5 centimeters as the average length of the patella, and we have further assumed that the quadriceps tendon drops the entire 2 centimeters when the patella is removed (which is not entirely true in view of the thickness of the quadriceps tendon itself) We have computed that this portion of the quadriceps tendon becomes lengthened to about 6.4 centimeters or a gain of about 1.4 centimeters.

Since muscle power is directly related to the length of the individual fibers and hence to overall contractile length it can be readily seen that a gain in length of 1½ centimeters would be disastrous to function both in strength of the quadriceps and in range of extension of the kinee. This point has not been adequately clarified and for this reason we misst that the elimination of the slack is the important principle in the operation and that it makes little difference whether the patella is reached through a transverse parapatellar or other approach.

The operation we have used is as follows (Fig 2) The patella is approached through a short median parapatellar incusion. A straight longitudinal incusion is made through the quadriceps expansion in the midline of the

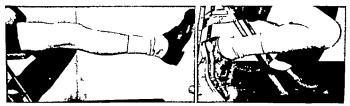

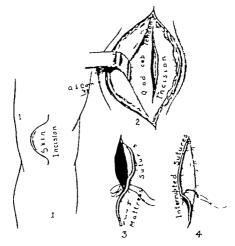

Fig. 1 Patient A.L., aged 24 years. Chondromalacia a patellac of right knee a and b, Photographs made 8 weeks

Fig. 3 left. The are is assumed to equal its chord. Appheation of Pythagurean theorem above above to qualify the property of t

patella, extending 1 centimeter above and below the limits of the bone. The expansion is then removed by sharp dissection left is intact as possible and the patella is removed after cutting through the synovial attachments The quadriceps tendon is then plicated laterally a distance of 16 centimeters at the midpoint and tapering toward both ends. This figure is arrived at as before by assuming the thickness of the patella 15 2 centimeters, the width as 4 centimeters, and the slack to be eliminated being computed a 1 6 centimeters (Fig 3) In actual practice if one merely plicates all the available there in the lateral direction without tension the result will be the same However this plica-

tion must be performed with the knee in full extension since in flexion the slack will be leasened and the computations made become invalid. The plication is done with No cosilk, reinforced with single sutures. The subcutaneous tissue and skin are closed as usual

Postoperatively the patient is immobilized in balanced suspension with the knee in full extension for 1 week and is then started on active exercises. Quadriceps setting is begun in 24 hours. Patients can usually begin weight bearing within 2 weeks.

The conditions for which patellectomy is most often indicated are recent comminuted fractures old fractures with roughening of the articular surface of the patella or femoral condyles chondromalacia patellae and dislocations habitual or recurrent of traumatic paralytic, or congenital origin. In addition removal of the patella may be indicated in the treatment of degenerative arthritis local septic lesions and tumors of the patella.

#### CLINICAL MATERIAL

Nineteen total patellectomies are now avail able for study data are presented in Table I In patients with chondromalacia patellae

as the underlying pathological process there

has been a normal range of motion preopera tively but with associated knee joint symptoms. Postoperatively in all cases, there has been a rapid recovery of normal motion with a subsidence of all symptoms.

In those cases in which there has been limi tation of joint motion preoperatively as in the compound fractures there has been a definite improvement in the range of motion although normal motion has not been attained We believe that in these cases failure of return of normal motion is due to associated intra articular damage found in all cases on the roentgenograms and at the time of sur gery In this respect it is noteworthy that there was normal motion preceding and fol lowing patellectom; in patient M J with a comminuted fracture of the patella due to a perforating bullet wound in whom there was no demonstrable associated joint damage All natients have been relieved of their knee loint symptoms and excellent function has resulted in spite of the limitation of motion.

We have concluded that whereas in all cases the patient is allevanted of his knee joint symptoms and has shown an improvement in or normal restoration of motion this postoperative return of joint motion has been

conditioned by the range of motion entire prior to surgery

#### CONCLUSIONS

I While we hold no brief as to the incision used for removal of the patella, we believe that the median parapatellar skin incision and the longitudinal incision of the tendon are best adapted to the method of lateral plication.

2 The slack to be eliminated by the method of lateral plication has been computed to be 16 centimeters with the kine in full extension.
3 In this series of 19 patellectomies, (so compound comminuted fractures, 8 cases of chondromalacia and z ununited simple facture). all patients have been relieved of kine iolaint symptomia.

Whereas all patients have shown improvement in or normal restoration of function postoperative return of function has been coditioned by the range of motion eristing prior to surgery. Those patients who have had a normal range of motion before surgery will regain a normal range of motion following removal of the patiella those patients will imited motion preoperatively due to associated joint damage have shown a measurable improvement in range of motion.

# BRONCHOPNEUMONIA FOLLOWING ETHER ANESTHESIA IN OBSTETRICS

HOMER C HARTZELL, M D, and EDWARD P MININGER, M D Cleveland Ohio

SERIES of cases of bronchopneumonia has been observed in patients on the obstetrical service at Cleveland City Hospital These bronchopneumomas observed within a few days following delivery were variable in extent transient in nature and were not associated with clinical evidence of serious illness. They were discovered in almost all cases by means of a roentgenogram of the chest made to investigate the significance of slight fever or rales in the chest developing after delivery. The anesthesia in these cases consisted of ether admin istered usually by the open method and preceded by varying quantities of barbiturate and other premedication. The mechanism by which the pneumonias were produced was probably the aspiration of mucus or vomitus during or following anesthesia. Other factors which may be considered are suppression of cough reflex and retention of secretions due to the irritation of ether

Further study of these cases was undertaken because of the frequency with which they were observed and because some of them were in correctly diagnosed.

#### REVIEW OF LITERATURE

A search of the literature revealed that little attention has been paid to aspiration pneumonia as a complication of anesthesia in obstetrics. Hall in 1940 called attention to aspiration pneumonits as an obstetric hazard by reporting 15 cases of aspiration pneumonia following delivery. His cases were of a serious nature since 5 died and several others required prolonged hospitalization. He commented that the aspiration of solid material into the trachea or bronchial tree might produce death from respiratory obstruction, while the aspiration of fluid material produced some

From the departments of Radiology and Obstetrics and Gyne cology. Cleveland City Hospital, School of Medicine. Western Reserve University. sort of chemical pneumonitis. He discussed a number of factors including diet prior to delivery position of the patient during ancethesia, and premedication which he thought might be related to the problem of aspiration of gastric contents. Autopsies were obtained in 2 of his 5 fatal cases. One showed both lungs full of a diffuse wet consolidation with air present only at the extreme apexes. The second was found to have both lungs col lapsed and the bronch of each lung filled with dark colored contents, apparently spinach or some other dark food.

Meurin in 1941 reported a senies of 7 deaths occurring in Essex County New Jersey in a period of 4 years, developing during or soon after labor and directly caused by the aspiration of stomach contents. He stated that in addition to these 7 cases, many other deaths had occurred which were probably also of this nature but which were not included in his report due to lack of accurricy of the available information or because of their controversial nature

#### SUMMARIES OF TYPICAL CASES

CASE 1 V M a white woman 22 years of age was admitted to the tuberculosis division of City Hospital on August 26 1944 Four days prior to her admission, following a labor of 15 hours duration she was delivered of a healthy infant at a maternity hospital elsewhere in the city. Ether anesthesia was administered for 40 minutes preceded by seconal medication and was followed by vomiting Evi dences of bronchopneumonia appeared and on the day following delivery she was transferred to a gen eral hospital At this hospital a roentgenogram of the chest made 2 days following admission showed irregular mottled and feathery shadows of increased density distributed symmetrically throughout all of both lung fields. Since the radiologist interpreted these changes as due to pulmonary tuberculosis, the patient was transferred to the tuberculosis division of City Hospital. On admission she was afebrile did not appear ill but presented scattered inspira tory musical rales bilaterally. The admission roent genogram of the chest, made 6 days following del ivery again showed diffuse bilateral mottled infil

Fig Case Fytensive patchy symmetrical bilateral bronchoppeumonia

tration less extensive than that observed on the submitted reenigenogram. Because of the symmetry, of her pulmonary disease the healthy appearance of the patient and the absence of pulmonary symptoms, pulmonary sarcodons was suspected. An othe roentgenogram of the chest made 10 days fol I wing admission showed the pulmonary infiltration thave undergone complet resolution. Since the rapidity of clearing of the inhiltration excluded both pulmonary tuberculosis and sarcoidosis it was evil

Fig. 3. Case 4. Dense bronchopneumonic infiltration in right upper and lower lung fields

Fig. 7 Case 3. Deme coalescent infiltration in white lower two-thirds of right bung field, and left hilless.

dent that the process represented a widespread brachoppeumonia. The patient was dischared as September 16 1044 to the care of a private physical

CASE 2 F N a colored woman 12 years of age, was admitted to the obstetrical service on March 13. 1044, in active labor Seconal was administered in dose totalling 3 grains as premedication. Delvor was effected following a labor of 31/2 hours duration Ether anesthesia was employed \omning of per ticulate and fluid gastric contents occurred durage and immediately following anesthesia. Dyspace and cyanosis developed. Bronchoscopic aspiration # immediately performed with rebel of dyspace, to lowed by the administration of sulfathiasole for a period of 3 days. The temperature rose to 15 degrees Centigrade for a period of I day after has it remained normal Scattered rales were promi throughout the chest. The total white count on the day following delivery was 12,800 white cells per cells millimeter A roentgenogram of the chert mack t day following delivery showed the presence of coales ce t poorly demarcated shadows of increased design distributed symmetrically throughout both fields interpreted as bronchopneumonia. Following the initial episode of obstructive dyapnes, the paties did not show evidence of senous illness. A second chest radiograph made 8 days following delact) showed complete resolution of the bronchoped monta. She was discharged April 3 1944, 11 days following her hosp tal admission.

vomiting A roentgenogram of the chest made 3 days following delivery showed the presence of motiled and conglomerate shadows of increased density in volving the lower two-thirds of the right lung field and the left fillum area interpreted as broncho pneumonia. Despite the extent of the infiltration as observed roentgenologically the patient did not appear ill and her temperature did not exceed 38 2 degrees Centigrade. An x ray film of the chest made 4 days later showed the bronchopneumonia to have undergone complete resolution. She was discharged in good condition on April 4 1941.

CARE 4 E S a colored woman 19 years of age was admitted to the delivery room on February 12 1045 Delivery was effected under ether anesthesia preceded by atropine. The patient vomited shortly following delivery. Twelve hours later she developed

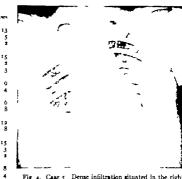

Fig 4. Case 5 Dense infiltration situated in the right upper lobe

a shaking chill and her temperature rose to §8.8 degrees Centigrade. A roentgenogram of the chest made on the day of delivery showed mottled shadows of increased density in the lower and medial portion of the right lung tield and in the left fillum area interpreted as bronchopneumonia. Sulfadazine therapy was begun. The patient remained febrile for only i day and recovered uneventfully. Another roentgenogram of the chest made 6 days following admission showed the pulmonary infiltration to have undergone complete resolution. She was discharged 8 days following admission.

CASE 5 B J a white woman 19 years of age was admitted to the obstetrical service on November of 1943 She was delivered under ether anesthesia pre ceded by morphine scopolamine medication follow ing a labor of 15 hours duration. After delivery she developed fever rising to a maximum of 38 4 degrees Centigrade A roentgenogram of the chest made 1 day following delivery showed a dense mottled infil tration in the upper lobe of the right lung interpreted as pulmonary tuberculosis. Although she did not present clinical evidence of serious illness she was treated with sulfathiazole for a period of 3 days. A second chest roentgenogram made o days following delivery showed the infiltration to have undergone complete resolution indicating that the original diagnosis of pulmonary tuberculosis was erroneous. She was discharged in good condition on November 21 1043

#### EVALUATION OF STUDY

Information concerning the 20 cases comprising this series is included in the accompanying tabular summary of the vessel markings has been found sug gestive of pulmonary hyperemia. None of the patients have shown mediasinal displacement or other evidence of massive stelectasis.

Clearing of the infiltration was rapid in most cases and complete in all. Fifteen of 18 cases in which serial films are available showed complete clearing in 1 week or less. The time of clearing in the other 3 cases is not known with certainty but complete disappearance of the infiltration was demonstrated on the eighth, ninth, and twenty first days, respectively

On strictly objective criteria, a roentgenologic diagnosis of aspiration pneumonia is not possible, but its recognition is usually easy if the roentgenologist has the clinical findings available to him, and if he is familiar with the condition. It may be confused chiefly with pulmonary tuberculous sarcoidous atelecta sis pulmonary edema, and other pneumonias. It is differentiated from both pulmonary tu berculosis and sarcoidosis by its rapidity of clearing as seen on serial films. It differs from lobar or massive atelectasis in its patchy character and in the absence of mediastinal displacement. Dependence must be placed upon the clinical findings to differentiate it from bronchopneumonias and pulmonary edemas of other etiology

It is evident that a roentgenogram of the chest made shortly following delivery may be a confusing diagnostic measure if its purpose is the detection of early pulmonary tubercu losis. Chest roentgenograms made for this purpose should be taken either prior to delivery or 2 weeks or more following delivery.

#### CLINICAL ASPECTS

The immediate sequel to vomiting during anesthesia has been respiratory distress. In 1 of the cases, this distress was sufficiently serious to require bronchoscopic aspiration for relief. In the remainder more simple measures proved adequate. There were no fatalities in this series, although the possibility of an immediately fatal issue is indicated by the reports of Hall and of Meurian.

The height of the fever manifested in these cases is indicated in the accompanying tabular summary. It was unusual for fever to be sus-

tained at a high level most of the patients presented one or several spikes of ferer with prompt fall either to normal or to a level below 38 degrees Centigrade. None presented the appearance of semous illness, and in none were clear-cut localized physical signs of consolitation, other than rakes, discovered. A sight leucocytosis, averaging 10,000 to 12,000 which cells per cubic millimeter was present in some

#### PATHOGENESIS

Two chief questions arise coocening the origin and nature of these bronchopneuments, namely what is the nature of the pathologic change in the lungs, and what is the explantion for the benign clinical course observed in

these patients?

It is generally recognized that, in addition to the classical forms of massive stelectus, smaller areas of lobular or paticly attection may occur as the result of occlusion of the bronchiolar radicles. It is probable that the shadows seen in the roentgenogram are a part due to such patches. Another factor contributing to the pulmonary changes in the raction of the lung tissues to the limiting particular contents, namely hyperemia, henoring-edemia, and exudation. Finally areas of laterial pneumonia may occasionally superview in areas in which virulent organisms have been appeared to the contents.

implanted. The failure of the cough reflex to expel the foreign material from the bronchial tree is probably in part due to the massiveness of the aspiration, and in part to the flindity of the aspirated material. Archibald and Brown have shown that cough, instead of expelling material from the bronchial tree, may actually cause at to be driven deeper into its rambotions. In their experiments upon animals, lodized oil was disseminated in the bronchal tree by cough, while thick tenacious sputum, being a heavier substance, was expelled. The dissemination of iodized oil by cough is a matter of common observation in broncho graphy On the basis of the experiments of Archibald and Brown, it is probable that gartric contents, because of their fluid nature and alight viscosity are widely disseminated in the bronchial tree by cough, and methiciently and incompletely expelled.

The benign course of these bronchopneu onias has been noteworthy One factor reconsible is their incidence in a group of young calthy women without evidence of cardiac or ulmonary disease A more important factor s the probable presence in these patients beause of their age of an adequate gastric acidity, inhibiting the growth of pathogenic

Other than coincidence (suggested by the bacteria. reported deaths in other series) the only fac tors known to have prevented immediate death from asphyxiation have been postural drainage of the bronchial tree, and its aspira tion by catheter suction in r instance bron choscopically for relief of respiratory distress.

### FACTORS PECULIAR TO OBSTETRICAL ANESTHESIA

A number of factors may play a part in the frequency of aspiration pneumonia in obstet ncal cases. First is the frequent necessity for administering an anesthetic when the pa tient's stomach is laden with food Second is the possible effect of premedication by barbi turate or by morphine in depressing protective reflexes or inducing vomiting Third the depth of anesthesia demanded in good obstet ncs is dangerously near the level at which vomiting may readily occur even when ex pertly administered Daily observation sug gests that the time of gastric evacuation is prolonged in labor and Meurlin states that

a delayed emptying time of the stomach during labor is a factor which should be kept in mind.' Finally vomiting is occasionally seen in the latter part of the first stage of labor and during the portion of the second stage of labor preceding anesthesia This may occur independently of medication and is probably of reflex origin.

# PREVENTION AND TREATMENT

The well known measures of postural drain age of the bronchial tree and its aspiration by catheter suction or bronchoscopically are the recognized methods of treating vomiting and aspiration during anesthesia.

The aspiration pneumonias in this series have not been of sufficient clinical seventy to require the use of chemotherapy nor did

. ...

chemotherapy affect the course of those pa tients in which it was used

The administration of an emetic in early labor to the woman who has recently eaten solid food has been practiced in this community Gastric evacuation by induced emesis, when carefully executed, might prevent the

postanesthesia vomiting and aspiration of The properly trained anesthetist will be particulate matter

able in most instances to maintain his patient in the narrow zone of anesthesia in which the labor processes are allowed to continue with out the development of vomiting

## SUMMARY AND CONCLUSIONS

1 A series of 20 cases of bronchopneumonia was observed at Cleveland City Hospital which developed following obstetrical delivery in which ether inhalation anesthesia was used

2 Their chief cause was the aspiration of gastric contents as a result of vomiting The possible contributory role of the following factors was discussed (1) preanesthetic med ication favoring suppression of the cough reflex, (2) prolonged gastric evacuation in labor (3) fluidity of gastric contents favoring their dissemination in the bronchial tree

3 The bronchopneumonias varied in extent from small isolated patches to extensive bi lateral infiltrations. They were observed in all portions of the lung fields.

4 Chincally they did not prove a cause of serious illness and no fatalities resulted Chemotherapy by sulfonamide drugs was

5 Roentgenologically the problem was one apparently not effective of differential diagnosis, requiring differentia tion from pulmonary tuberculosis, sarcoidosis other pneumonias pulmonary edema and atelectasis

## THE RETROGRADE LYMPHATIC SPREAD OF CARCINOMA OF THE "RECTOSIGMOID REGION

### Its Influence on Surgical Procedures

ROBERT P GLOVER, M.D. and IOHN M WAUGH, M.D., F.A.C.S., Rochester Minnesons

TEW organs of the body have been subi tected to more intensive and exhaustive study in recent years than has the rectum This is particularly true with reference to carcinoma and its notentialities in this reman. Needless to say we are still for removed from an understanding either of its cause or of its specific cure although admit tedly great strides have been made especially with regard to its surgical treatment. Those advances that have been made are based on a more thorough understanding of the nature of cancer of the rectum including the form which it is likely to assume its rapidity of growth, its mode of spread and its final out come. Here as elsewhere it has been learned that malignant disease with perhaps some few exceptions, can be adequately controlled only by complete externation, hence the innumerable surgical methods and modifications that have come into practice.

Movnihan in 1008 made the significant statement that the surgery of malignant disease is not the surgery of organs it is the anatomy of the lymphatic system Nowhere is this more applicable than to malignant disease of the rectum. It is toward the anatomy of the lymphatic system that the greater por tion of this study has been directed. Many investigators in the past and present have de voted much of their time to its study and the results of their work as well as the conclusions of this research will be correlated in an at tempt to determine what an adequate method of treatment for carcinoma of the rectum and particularly of the rectosigmoid region implies.

From the Mayo Foundation and the Division of Surgery Mayo Chalc.

Mayo Cluic.

Abridgment of thesis submitted in September 944, by Dr Glover and accepted in November, 1944, by the Faculty of the Graduate School of the University of Minnesota in partial fulfilment of the requirements for the degree of M.S. in Surgery.

If as has been the dream of surreous for many years, cancer of the rectoslement and upper part of the rectum with its involved diseased region can be removed, with restoration of normal continuity to the bowel and preser vation of sphincteric control, a great contribution will have been made. It was with meh an aim in more that this study was more taken for should it be feasible from a pathologic standpoint an impetus for refinements in survical attack and technique will surely fol low: As carcinoma of the rectum represents some a per cent of all cancers (1 15) # is evident that the number of patients who might be concerned is considerable and any pathologically sound attempt to avoid the construction of an artificial anus will be well repaid. Such attempts have been numerous and with good, result when properly carried out but have been frowned on by many who believe them to be more semational than radical, basing their belief primarily on the work of Miles.

### SPREAD OF CARCINOMA

Malignant disease may spread primarily in one of three ways by local extension from its site of origin by invasion of venous channels, and through the lymphatic system. An evaluation of any therapeutic approach to cardnoma in a given region must therefore take into its scope each of these avenues. Although an extensive literature concerning the first two of these modes of spread exists, the ongnal work of this paper deals only with certain aspects of lymphatic spread and consequently discussion other than of the lymphatics must necessarily be limited to a few short statements.

Local extension Carcinomas of the recto argmoid are relatively slow-growing malginal lesions. Microscopically three quarters of

them are of low grade, so that one would ex pect considerable local growth before any widespread metastasis has occurred. W J Mayo (25) emphasized this point in 1910 and resterated it repeatedly (26 27) as have other writers (4 33) Indeed, in his experience local extension more than any other factor, including lymphatic and hepatic involvement, was the common cause of inoperability That distant metastasis may occur while the mass of the disease remains localized is of course well recognized and indisputable but by and large it may be stated that a considerable period elapses in most cases before this occurs It is obvious therefore, that all locally in volved tissues must be removed at the time of operation and to accomplish this end it is absolutely essential that wide excision through healthy tissues be practiced

Venous spread Once carcinoma has spread into venous channels with the formation of malignant thrombi and dispersion of malig nant emboli, no surgical procedure however radical can be devised to rid the patient of his affliction. Were such a sequence of events customary the prognosis for cancer of the rectum would indeed be grave Fortunately this does not obtain although investigations within the last decade tend to show that it is a more frequent occurrence than was formerly suspected

Intravascular invasion seems remarkably constant, occurring in approximately a fifth of all cases of malignant lesion of the lower part of the colon (8 13 34) As would be ex pected, the higher the grade of malignancy the higher becomes the incidence of venous involvement and the greater the probability of visceral metastasis (3)

Perhaps the most significant observation concerning venous spread was made by Clogg in 1904 He noted that when dissemination via the blood stream occurred it frequently did so before the disease had spread to lymph nodes. Recent studies (13) have confirmed this impression and enlarged on it to show that most vascular invasion originates within the involved intestinal wall itself or within the immediately adjacent perirectal tissues and not from more distant extensions. Consequently although sharply limited and seemingly favorable for surgical removal, a rather innocuous-appearing cancer may prove as deadly as the most widespread and perforat ing types. Such cases explain why the rate of cure declines in direct proportion to the degree of penetration even though no involvement of perirectal fat or lymphatic network be found It must be obvious therefore that the threat of venous spread demands early rather than radical surgical intervention the latter being directed more especially against local and lymphatic expansion

Lymphatic spread As carcinoma spreads through the ramifications of the lymphatics in a most systematic and relentless manner, the problem of its control must be met with equal thoroughness and determination. To do so en tails an intimate knowledge of all pathways over which such an advance may occur. The literature contains several detailed and exact studies (9 32 35) to which reference may be made with considerable profit and from them Figure 1 has been constructed.

Anatomic review Considering the anus and rectum as one continuous tube at may be divided into three regions corresponding roughly to the areas supplied by the inferior. middle and superior hemorrhoidal arteries. The inferior region is the 25 centimeters of anus proper terminating superiorly at the pectinate line The middle region extends upward from the pectinate line to a point just above the insertions of the levator and muscle The superior region extends from this point to the sigmoid colon and terminates approximately at the level of the third sacral verte bra. This latter is the largest of the three regions.

The lymphatics in all of these regions origi nate in a rich network of tiny lymph spaces the extremely close meshes of which extend throughout the mucosal, submucosal and intermuscular layers Although continuous diversified connections of this network have been said to exist between all three regions for the most part they may be found to unite into their own collecting trunks, which further join to terminate in lymph nodes after the full thickness of the intestinal wall has been traversed. Thus the direction of flow is essentially at right angles to the long axis of the bowel.

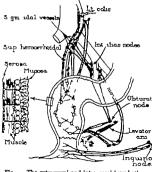

Fig The extramural and latramural lymphatic systems of the rectum (intramural system after Leitch)

even though many small intermediary branches may course in any direction en route to their final destination. In other words lymph potentially able to spread from anus to sigmoid in whole or part via these small channels never does so a point which will be discussed in some detail presently under intramural spread. Having thus arrived in the collecting trunks drainage proceeds according to definite pattern.

1 Inferior and middle regions. Although drainage from the inferior and middle regions is not strictly a concern of this work, it may be pointed out in passing that most if not all of the lymph originating in the region at the same level as, or immediately above, the in sertions of the levator ani flows upward, joining the pathways of the superior region. Some may however spread laterally along the levator muscles, either superior or inferior to them and some may also spread caudally through the adipose tissue of the ischiorectal fossa. Thus the lymphatic pattern of the middle region might possibly in certain instances be designated as being 'perincopelviabdominal (Fig 1)

2 Superior region. \umerous efferent trunks pass through the muscular coat at

different levels. Most frequently these trunks become satellites of the branches of the sme rior hemorrholdal vessels, usually two for each artery After perforating the rectum they me obliquely unward and backward to reach the nodes in the mesorectum. In their perirectal course they traverse several small nodes placed on the muscular layer and covered by the serous coat of the rectum (nararectal nodes of Gerota) These nodes are found expectally in the region of the ampulla, the lowest immediately above the levator ani. The amenor nodes however may be found projecting underneath the serous coat and are minute The true mesarectal nodes of considerable are are usually grouped around the smeror hemorthoidal artery and may be regarded as the true regional nodes of the superior region of the rectum. The flow of lymph in these channels is unward, although it is concervable that a dam or block to the natural moward course might cause lymph to flow in a retrograde manner Normally however the lymphatic drainage of the superior region of the rectum is only abdominal in direction (35) a point which cannot be too strongly emphasized Whereas dramage from the inferior and middle regions of the rectum may be perincopelyabdominal with anastomoses in the posterior part of the vagina and the levator an muscles, drainage from the upper part of the rectum has no direct anastomosis with pelvic organs unless it be by long tedious and unnatural retrograde flow down the surface of the rectum in the face of complete unward blockage as suggested previously

Pathologic consideration. Having this become well versed in the normal course of lymphatic drainage in and from the rectum it is now possible to appreciate more fully by mailignant processes avail themselves of these channels. Discussion will be greatly facilitate by dividing the lymphatic system as a who into intramural (from mucosa to scross) and extramural (from serosa to regional nodes) components.

I Intramural (Fig I) Carcinoms of the rectum takes its origin from altered mucosi cells of the rectal hung usually stated as unique deep in the crypts of Leberkuchn. From this tiny focus it may apread either by direct

extension and invasion of small lymph meshes from its margins or directly through the thick ness of the rectal wall Marginal extension is greater and more rapid transversely around the bowel than through the rectal wall but even transverse extension is extremely slow 6 months being the estimated time for carcinoma to travel approximately a quarter of the way around the lumen Advance through the submucosal and muscular layers is equally slow and the scrosal covering has usually not been reached until the growth has traversed three quarters of the circumference of the bowel or until some 18 months have elapsed The circular and longitudinal muscles are pierced by radial channels thus giving free communication for malignant cells to travel between submucosal intermuscular and subserosal plexuses.

Cole was able to show that whereas carci noma spread more widely in the submucosa han on the mucosal surface and still more videly in the muscularis there was no evi dence of longitudinal permeation of the intestinal wall beyond the microscopic edge of the growth. Other studies appearing at approxi mately the same time all substantiated this view (5 22 30) Monsarrat and Williams demonstrated that as a rule longitudinal spread occurs only to the distance of about 2 centimeters above or below the gross mucosal edge of the lesion and that this invasion is greatest in the subserosal portion In more recent years ample evidence (12 20 21 24 20) has accumulated indicating the improba bility of any widespread dissemination along the course of intestinal walls comparable to the spread along the wall of the stomach that may occur in cases of gastric carcinoma. Apparently described anastomotic channels to any great distance are potential rather than actual. Leitch has expressed the belief that the lymphatics of the mucosa do not exist as a continuous plexus but are arranged in a decussating arborescent pattern from the collect ing stems which pierce the circular muscular coat. Spread in the intermuscular lymphatics is just as limited (Fig 1) It may therefore be stated that intramural dispersion alines it self closely with observed gross and microscopic extensions of the growth and plays no

part in the demand for extensive radical sur gical intervention

2 Extramural. By far the most important mode of extension extramural spread has accordingly been the subject of most well di rected research to date Because of its sup posedly widespread potentialities carcinoma at the rectosigmoid juncture has for the most part been subjected to the same treatment as has carcinoma lower in the rectum with re moval of perianal skin rectal sphincter and the whole pelvic colon Evidence in the litera ture combined with that of this study will demonstrate rather conclusively however that many growths high in the rectum lend themselves admirably to procedures far less radical than this and more acceptable to the patient but equally effective as far as the disease process is concerned. Close scrutiny and attention to detail will reveal a loophole which up to the present although noted by several investigators has failed to become widely rec ognized as such True it is that a few surgeons have explored these possibilities to their own satisfaction but the majority either are un aware of the opportunities afforded or have been misled by existing pathologic studies

In accord with anatomic findings Miles observed that malignant processes might extend in an upward lateral or downward direction although in his study he made no attempt to give the exact location of the lesions employ ing these various pathways The common course is upward for it occurs in every case regardless of the site of the lesion from anus to sigmoid

Lateral dissemination refers to that which courses along the levator an muscles, the coccygei base of bladder cervix or base of the broad ligaments to terminate in the internal iliac nodes Miles has encountered such in volvement in several cases both in that por tion of the levators immediately adjacent to the bowel and far laterally near the pelvic walls. Gilchrist and David made similar observations in 4 cases of their series Coller Kay and MacIntyre in 6 and Gordon Watson and Dukes (18) in 1 case That lateral dissem mation may occur therefore is unquestioned and when one is dealing with low lying growths it must be given due consideration

Above the pertinate line

Downward invasion, as Miles used the term refers to soread along the inferior hemorrhoidal vessels through ischiorectal fat and Alcock s canal, eventually to internal iliac nodes. Miles discussed a specimen removed by abdominoperineal resection in which the cancerous process had taken such a course Other evidence that he presented was derived from records of postoperative recurrent growths occurring in the posterior wound. Whether these growths may be regarded as of true lymphatic origin or as occurring by direct invasion is a matter for debate Gordon Watson and Dukes were undecided as spread in 2 of the 3 cases in which they noted ischiorectal involvement appeared more likely to be by direct continuity

The long unbroken chain of lymph nodes originating in the small pararectal nodes of Gerota deeply placed in the pelvis posterior to the rectum and extending through the larger superior hemorrholdal group on into periaortic channels constitutes the upward and primary lymphatic drainage of the rectum Neoplastic lesions situated anywhere within the pelvic colon sooner or later advance over this well traveled route. In the upper part of the rectum it is the only lymphatic drainage for malignantily lymphatic drainage aroilable for malignantil invasion.

unless, on further investigation, ideas concerning the importance of recently described perineural or perivascular (34) networks are

confirmed. This unward spread proceeds in an orderly manner so that on specimens from cases of advanced carcinoma there is a sequence of involved nodes stretching from the primary growth to the point of ligature of the inferior mesenteric vessels. This procession is usually from node to node but occasionally it is discontinuous with considerable intervening gaps, due to the presence of several upward tracks running so to speak over the same roadhed. Numerous paths course directly to nodes at the bifurcation of the superior hemor rhoidal vessels, a few to the junction of the superior hemorrhoidal and lowest algoridal vessels, by passing all nodes en route and others to the junction of the left colic and inferior mesenteric vessels. Thus on occasion, intervening uninvolved nodes have been observed, so that it is impossible to state which node is the highest seat of metastasis unless all to a considerable height have been examined. Examples of this pattern have been shown by Grinnell Gabriel, Dukes, and Bussey (14) Wood and Wilkie as well as many others.

As no anastomoses of the lymphatics of the upper part of the rectum with those of pelvic organs exist, no lateral spread of carcinoma of the upper part of the rectum as described previously can occur via the lymphatics. In vasion by direct continuity may and does of course take place in direct proportion to the age of the growth.

Downward or retrograde spread along the course of the bowel through pararectal nodes although normally nonexistent may under certain circumstances be observed. In cases of advanced carcinoma in all probability beyoud the realm of surgical cure when the superior hemorrhoidal and inferior mesenteric nodes all or in great proportion become clogged with extensive metastasis cancerous cells may take the course of least resistance downward in this instance over the same pathways which normally carry only one-way traffic-upward (17) Examples of this in the literature are rare and may be seen in Table I. There it will be noted that only 8 such cases have been observed the node at a centimeters below the lesion (Gilchrist and David) probably being the only true demonstration of such retrograde flow. If therefore retrograde metastasis is so rare and there are no other lymphatic anastomoses between the upper part of the rectum and pelvic structures should it not be reasonable that such facts be more widely applied in the surgical attack on lesions of the upper part of the rectum and rectosigmoid region? In order to be certain that such a stand could be taken on factual pathologic evidence and in the feeling that examination of the portion of the rectum and perirectal tissues lying between the lower part of the sigmoid and the insertion of the levator an muscles would give the crucial answer long and tedious study was directed at this region by means of the following procedures.

### MATERIALS AND METHODS

One hundred surgically removed rectums containing adenocarcinoma of the upper part of the rectum the rectosigmoid or the lower part of the sigmoid were obtained from the Division of Surgical Pathology of the Mayo Clinic An attempt was made to secure only those specimens which represented far ad

vanced disease so that the greatest possible spread of neoplastic cells might be contained therein A choice from 2 206 such specimens was made only those removed by combined abdominoperineal technique being used to be assured of the maximum tissue for dissection

That these specimens constituted a group containing most extensive malignant lesions is evidenced in several ways. All of the adenocarcinomas were of Duke s type C (11) that is all had metastasized to adjacent and regional lymph nodes Grossly oo were ulcera tive and I was polynoid. Ulcerative lesions of the colon are the most malignant and invasive type. Twenty nine had advanced to perforation Eighty three of the ulcerative lesions were annular. As to their site of origin in the upper part of the rectum and above o 5 centimeters was the average distance from the lower gross mucosal edge of the lesion to the anorectal or pectinate line. This fact was ascertained by measurements of the formalin ized specimens as well as by those recorded on the pathologist's report made at the time of operation and further corroborated by proctoscopic examination before operation,

It was originally intended to select the cases in equal number from each of the four grades of malignancy as classified by Broders thus making comparison of results more uniform than it would be otherwise. However as 75 per cent of rectal lesions are of low grade (1 and 2) it was impossible to secure enough specimens of the higher grades (3 and 4) which had not previously been used for other studies to fill in the required quota. Rather than sacrifice accuracy for statistics, all those lesions of higher grade which fulfilled the pre-

For Case Location of the curcinoma with reference to the bowel, lymphatic and vascular systems (care-norms, shaded area involved nodes, black dots uninvolved nodes, open dots)

viously stated requirements were chosen first -27 in number-and the difference up to 100 -73 cases-was obtained from the more plentiful exercisors of low grade (Table II)

Two methods for the complete examination of the lymphatic region of an organ are available. The injection method the one most recently used and especially adapted to the examination of fresh tissues, is that described by Spalteholtz and modified by Gilchrist and David. This type of investigation is accurate and has enabled its advocates to find many more nodes than they were previously able to locate by gross dissection of fresh specimens.

The other method is the more time-con suming and laborous gross dissection. This is the only method which can be used for tissues long immersed in formalin and may with application produce as satisfactory results as the injection method. Suffice it to say that the dissection method yielded results quite comparable to any other for in those 5 cases of this series in which all the nodes on the entire specimen were examined an average of 60 nodes per specimen was found, the largest number being 82 the smallest 44.

By gross dissection then each of the too specimens was minutely examined from the lower gross mucosal edge of the lesions present to the anna Serial sections were cut each annroximately i centimeter in width the incisions beginning in the perirectal fat and being carried into the mucosa. The numerous slices thus produced were allowed to remain hinged on the miscosa so that accurate meaurements could be taken concurrently all lymph nodes were removed and each was carefully labeled not only as to its relationship to the lesion itself but also as to its postion on the vascular tree. From these data all nodes were charted on disprenimatic sketches of the pelvic colon which were drawn to scale and on which each lesion had previously been outlined also according to scale. An average of II nodes per specimen was found between the lumits outlined previously the largest number being 53 the smallest 2 A total of 1.330 nodes was found during the course of the whole study including nodes examined behind and above the lesions in the few cases indi-

cated later

Each node was then subjected to microscopic examination by the frozen section
technique used in this case for screening those
nodes metastatically involved from those uninvolved All nodes containing any evidence
of cancerous cells were further sectioned and
stained with hematoxylin and cessin for study.
Those found to be free from involvement were
not examined further. One thousand four
hundred seventy nine sections were made.

### RESULTS OF STUDY

In 64 cases there was no spread dutal to the lower gross mucosal level of the lesion but in 36 cases there was dutal spread. In 27 of the 36 cases the nodal involvement was within the first centimeter and no lower in 6 it was between 1 and 2 centimeters but no lower and in 1 case each it was between 2 and 3 centimeters 3 and 4 centimeters, and 6 and 7 centimeters.

All those cases in which there were positive nodes from the lesion to 2 centimeters but so lower were considered to be of no particular significance for the reason given previously in the section on intramural spread. It will be

remembered that as malignant invasion proceeds from the mucosal to the serosal surface of the intestinal wall it does so in a more or less triangular fashion the base of the triangle being placed longitudinally along the long avis of the howel in the perirectal fat at the serosa. In advanced lesions such as these the greater involvement in the perirectal fat and serosa as compared with involved mucosa al ways extended 1 centimeter below and above the longitudinal diameter of the lesion as measured on the mucosa frequently extended to 2 centimeters in either direction and was occasionally seen at 3 centimeters. As a consequence all nodes within the first centimeter were found to be imbedded in carcinomatous tissue so that their removal for microscopic examination was in reality of academic interest only Four of the 6 cases in which lym phatic spread was 1 to 2 centimeters were in this same category. In the other 2 cases the involved nodes were immediately adjacent to but not actually imbedded in carcinomatous tissue. The nodes from the a cases in which nodal involvement was more distal however were further removed from directly involved tissues although malignant extensions from the local growth were considerably closer than the indicated distance as measured from the lower mucosal level of the lesion In summary therefore, of the 100 cases in which the tissues were thoroughly examined only 3 could be classified as exemplifying true retrograde metastasis of any significance

The obvious question now arises. Why did retrograde lymphatic permeation occur in 3 cases and not in the others? This problem en tailed the re-examination of those tissues in which retrograde spread had occurred For the sake of obtaining more complete evidence and also because 2 of the 6 cases with spread to 2 centimeters might be construed as in stances of downward spread all cases in which the distance was more than I centimeter were included in this additional study In the same manner as has already been de scribed all remaining nodes on the o specimens in question except as indicated were removed and subjected to sectioning and charting A detailed report was prepared for each case consisting of both clinical and

Fig 3 Case 2 For explanation see legend of Figure 2

pathologic features as they applied in each instance

### REPORT OF CASES

CASE 1 A white woman, 61 years of age registered at the Mayo Clinic July 14, 1917 with a chief complaint of rectal stoppage A detailed history revealed I year of rectal bleeding suprapubic un easiness ribbon like stools and finally almost complete obstruction and loss of 20 pounds (13 2 kgm) Physical examination gave negative results except for a large hard fixed encircling mass high in the rectum On July 23 1917 one stage perineoabdom inal resection was performed. During the operation a small suspicious nodule was felt in the liver. The patient was dismissed from the clinic on August 31 1017 after an uncomplicated recovery. The last report indicated her death in November 1917. No details were given. Grossly the surgical specimen contained a very extensive annular ulcerative le sion 7 by 6 by 4 centimeters mucosal measurement 6 centimeters above the pectinate line A total of 70 lymph nodes were found Microscopically the lesion was an adenocarcinoma grade 4 (Broders) For distribution and involvement of nodes see Figure 2 The lowest involved node was found between 1 and 2 centimeters below the lower mucosal edge of the lesion.

CASE 2 A white man, 36 years of age regustered at the clinic April 25 1034 with a chief complaint of constipation after 6 months of blood-streaked, nucoid rectal discharges dull abdominal aches and pains increasing constipation and loss of 7 pounds (3 2 kgm.) Physical examination gave casentually

Fig. 4. Case 3. A cross section through the perirectal insecs at about the midportion of the lesion as ulmstrated i. Figure 5. The solid carrinomatous area on the left corresponds to the double crosshatched area. I. Figure 5. The two nodes to the right above are also represented in Figure 5. They were found to be completely replaced with cancer cells. The block to the upward flow of lymph is obvious.

negative results except for a large encircling lesion especially prominent on the posterior wall high in the rectum This lesion was venfied by proctoscopic examination. On May 1 1934 one stage combined abdommopermeal resection was performed. At operation the liver was noted as clear. The patient was dismissed from the clinic on May 24 1934, after an uncomplicated recovery. The last report indicated death in December 1935 with extensive metastasis about the colonic stoma abdomen and liver Grossly the surrical specimen contained a huge ulcerative lesson 15 centimeters in diameter mucosal measurement to centimeters above the pectinate line A total of 55 nodes were found Microscopically the lesson was a colloid adenocarcinoma grade 4 Fo destribution and involvement of (Broders) nodes see Figure 3 The lowest involved node was found between and 2 centimeters below the lower mucosal edge of the lesion

AR 3 A white man 50 years of age registered at the clinc July 23, 1936 with a chief complaint of "bloody diarrhea." For 1 year he had had bloody rectal discharge and dull abdominal cramps with a final weeks of constant pans and constipation. He had lost 40 pounds (18 1 kgm) Physical examination revealed a huge hard irregular cauliflow if like mass in the rectum which was vended by proctosopic examination On July 27 and August 24, 396 two stage combined abdominoper lacel resection was per formed. The liver was clear but there was extensive apread to the bladder and around the left ureter. The nation left the clinc in September 23, 1936.

Fig. 5 Case 3. For explanation see legend of Figure Compare with Figure 4

without damessal but recovery had been uncompocated. The last report indicated death in April, 1015 but no details were given. Grossly the suppellayer imen contained an extensive an internative leason o by 8 by 5 centimeters, master incomments of the one of the suppellayer in the contract of the contractive ment 6 centimeters above the pectual necessary to two nodes only were removed and examined the others were allowed to remain as risk for photographic evidence as shown in Figure 4. Microsoically the leanon was arrowed in the properties of the Ford distribution and involvement of nodes see Faure 5. The lowest involved node was found between 2 and 3 centimeters below the lower mucosal eder

of the lesion CASE 4 A white woman 3 years of age regis tered at the clinic August 22 1938 with a chef complaint of duarrhea. For 3 months she had had colicky pams in the left lower quadrant associated with diarrhea, occasionally bloody She had lost 13 pounds (5 9 kgm ) Physical examination gave och tive results except for a mass with some fixation of the bowel on rectal examination. Proctoscopic ally a lesson was found involving the right and asterior walls of the lower part of the sigmoid colon. On August 29 and October 3 1938 two stage combined abdominoperineal resection was performed. The liver was noted as clear but there were impliant throughout the pelvic pentoneum. The patient dismissed from the clinic November 19 1938, in good condition after a mild postoperative armany infection. The last report indicated death on April 7 1941 from a recurrence. Grossly the sargest

Fig. 6 Case 4. For explanation see legend of Figure 2

specimen contained a perforated annular ulcerative lesion a by 3 by 3 entimeters mucosal measurement 16 centimeters above the pectinate line. A total of 83 nodes were found Alicroscopically the lesion was an adenocarcinoma grade 3 (Broden) For distribution and involvement of nodes see Figure 6 The lowest involved node was found between 6 and 7 centimeters below the lower mucosal edge of the lesion

The question arises in this particular case whether all the involved nodes shown below the lesson in Figure 6 represent true retrograde spread. As the lesion itself was in the lower part of the sigmoid a portion of the colon still maintaining a mesentery it seems probable that normal flow of lymph had occurred over the two lower rectosigmoid arcades both of which he below the lesion. This is consistent with the lymphatic drainage of the colon proper which differs from rectal drainage in that it may proceed along the axis of the bowel in either direction from a lesion until a vascular arcade has been reached at which point it courses in through the mesentery to large midline plexuses of nodes. In that event only the four lower carcinomatous nodes a span of about 3 centimeters would represent true retrograde involvement. However as

Fig. 7 Case 5 For explanation see legend of Figure 2 Compare with Figure 8

the original premise and conditions of study included all nodes below the level of the lesion all the nodes in Figure 6 will be considered as examples of retrograde spread

CASE 5 A white woman, 57 years of age registered at the clinic November 13 1939, with a chief complaint of increasing constipation of 8 months duration bloody stools and the continual sensation of a full rectum She had lost 17 pounds (7 ½gm) Physical examination gave negative results except for a large rectal mass which was confirmed by proctoscopic examination. On November 17 1039 and January 19 1940 two stage combined abdomin

Fig. 8. Case 5. Lesion from serosal surface. Because of the absolutely solid nature of the infiltrating carcinoma in the perirectal fath was deemed unnecessary to attempt dissection of the nodes behind and above the lesion in this

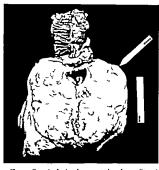

Fig. c. Case 6 Lesion from serosal surface split and laid open, showing the solid nature of the infiltrating cancer (see report of Case 6)

openneal resection was performed. The liver was noted as clear. The patient was dismused from the clinic March 18 1040 in good condition after a complicating postoperative thrombophlebits. The last report indicated death on April 12 1041 from a recurrence. Grossly the surgical specimen contained a large annular ulcerative lesion 7 by 6 by 5 centimeters mucosal measurement o centimeters above the pectinate line with two polyps one 5 centimeters below the growth and one I centimeter above it Twenty seven nodes only were removed and examined the others were allowed to remain in silv for photographic evidence as shown in Figure 8 Microscopically the lesion was a colloid adenocarci noma grade 2 (Broders) For distribution and invol rement of nodes see Figure 7 The lowest involved node was found 3 to 4 centimeters below the lower mucosal edge of the lesion.

Care 6 white man, 32 years of age registered at the cline December 2 1940 with a chief complaint of weight loss. For 3 months he had had rectal bleed go irrgence and bouts of diarrhea and constipation. He had lost 17 pounds (77 kgm.) Physical examination revealed a "mass felt high in the rectum which was confirmed by proctocopic examination. On December 7 1940 one stage combined abdominoperineal resection was performed. The liver was clear to palpation. The patient was duminsted from the clinic January 2 1941 in good condition. The last report on June 18 194 stated that he suffered from backache and pain down both legs. There has been no further communication. Grossly the surgical specimen contained an ulcerative lession 5 by 4 centumeters with direct extension.

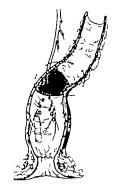

Fig. Case 6. For explanation see legend of Figure Compare with Figure 9

into perirectal tissues forming a mass 8 by 6 centmeters. The lesson was 8 centimeters above the pectinate I ne Only 9 nodes were removed and er arnined the others being allowed to remain is ris for photographic evidence as shown in Figure 9 Because of the absolutely solid nature of the infitrating cancer throughout all penrectal torses behind and above the lesson it was not considered necessary to isolate nodes in order to demonstrate their blocked nature Figure o demonstrates adequately the large dam-like mass extending around the bowel and effectively shunting advancing cardnoma in a retrograde direction. Microscopically the lesion was an adenocarcinoma, grade 3 (Broden) For distribution and involvement of nodes see Figure 10 The lowest involved node was found 1 to a centimeters below the lower mucosal edge of the leuon

CARE 7 A white woman 52 years of age, reptered at the chind June 6 1911 with a chief conplaint 1 bloody diarrhes." of 5 months with agic
of low backache She had not last weight. Physical
examination demonstrated a large, nother mans
the left posterior wall of the rectum which was onfirmed by proctoscopic examination. On June 10
and August 8 1911 two stage combined absentionperinced resection was performed. On September,
1911 the patient was dismissed in good credition
after complicating thrombophicibits, juniously
embolism and procursonia between stages of the resection. September 10, 912 a plastic operation sta

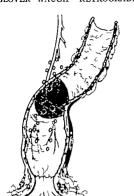

Fig. 1 Case 7 For explanation see legend of Figure 2 Compare with Figure 12. The small black rectangle is discussed in the report of Case  $\gamma$ 

1942 to April 1943 four courses of roentgen therapy were given. The last report on September 23 1943 showed the presence of some pelvic pain Grossly the surgical specimen contained an annular ulcera tive perforating lesion 5 by 4 by 15 centimeters, mucosal measurement 8 centimeters above the pectinate line. A total of 23 nodes were found. The small black rectangle shown on Figure 11 between 1 and 2 centimeters below the growth represents tissue removed under the impression that it was a lymph node. Careful microscopic examination in dicated that very little lymphoid tussue could be identified. There was however a small blood vessel with a small region of carcinomatous cells imme diately adjacent, which may have represented a tiny node completely replaced by cancer or may have been a rare demonstration of perivascular spread (Fig 12) In any event it was impossible to show adequate evidence of a block above this lesion as only 4 of the 14 nodes behind and above the lesion were involved. Microscopically the lesson was an adenocarcinoma grade i (Broders) For distribu tion and involvement of nodes see Figure 11 No involved nodes were found below the lower mucosal edge of the lesson.

CARE 8 A white man 62 years of age registered at the clinic September 8 1041 with a chief complaint of "alternate constipation and diarrhea. One year of constipation rectal bleeding parmidi move ments and a loss of 12 pounds (5.4 kgm ) were the main symptoms. Physical examination disclosed a high facel lesion in the rectum which was verified.

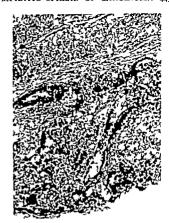

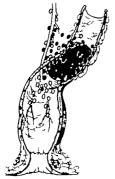

Fig 12 Case 7 Possible perivascular lymphatic spread as discussed in report of Case 7. The vessel is cut longitudinally the lumen appearing as a strand of cells in the upper right corner ×100

by proctoscopic examination. On September 25 and October 27 1041 two stage combined abdominopermeal resection was performed. The liver was clear The patient was dismissed on December 4 1941 in good condition despite a mild urmary in fection (postoperative) The last report on July 16 1043 indicated a loss of 15 pounds (6.8 kgm ) but no other evidence of recurrence Grossly the surgical specimen contained an annular ulcerative perforat ing lesion 7 by 6 centimeters mucosal measurement 12 centimeters above the pectinate line. A total of 56 nodes were found Microscopically the lesion was an adenocarcinoma grade 4 (Broders) For distributton and involvement of notles see Figure 13. The lowest involved node was found between 1 and 2 centimeters below the lower mucosal edge of the lesion.

CASE 9 A white woman 39 years of age registered at the clinic September 17 1942 with a chief complaint of constipation. For 2 years she had had recurrent rectal bleeding pain high in the rectum and increasing constipation. She had lost 8 pounds (3 6 kgm.) Physical examination revealed a palipable mass high in the rectum which was confirmed by proctoscopic examination. On September 23 1942 one stage combined abdominoperlineal resection was performed. The liver was clear. On October 16 1942 a course of roestigen therapy was given. The patient was dismissed October 30 1042 in good

I g 3 Case 8 For explanation see legend of Figure 2

condition after a mild unnary infection. The last report was on September 6 1943 when a check up at the clinic revealed no evidence of recurrence Grossly the unigical specimen contained an annular, ulcerative lesion 5 b) 4 b) 2 centimeters, mucosal measurement 7 centimeters above the pectinate hine A total of 44 nodes were found. Microscopically the lesion was an adenocarchoma, grade 4 (Broders) with squamous-cell metaplasia. For distribution and involvement of nodes see Figure 14. The lowest involved node was found between 1 and 2 centimeters below the lower mucosal edge of the lesion.

### SUMMARY OF REPORT OF CASES

Nine cases of carcinoms of the rectosigmoid demonstrating possible retrograde spread have been presented in detail with all pertinent chinical surgical, and pathologic data. In 5 cases all the nodes on the specimens were examined microscopically and in each case approximately two thirds of the nodes found behind and above the lesson were so completely clogged with cancer cells that any further drainage of lymph through their sinuses seemed impossible (Cases 1 2 4 8 9) In 1 case only a portion of the lymph nodes were examined. More than three quarters of these nodes found behind and above the lesion were completely involved with carcinoma and photographic evidence was sufficient to show

Flor 4. Case o. For explanation see legend of Figure

that all other nodes were likewise involved (Case 3) In 2 cases the tusues were so at tensively frozen in cancer that it wis deemed unnecessary to show any further owners of their complete involvement than that demonstrated photographically (Case 5 and 6) Case 7 remains an engma. Whether her terrograde spread demonstrated in this specimen represented an involved node or was a rate instance of periviscular lymphatic per meation is unanswerable. In any event there was not the high percentage of nodal movinement behind and above the kessor considered to be necessary to form a block to the upward flow of lymph.

It may thus be concluded that, when retrograde lymphatic spread down the course of the rectum and its ensheathing structures occurs, it does so as the direct result of a block occurring somewhere across its upward channels and that the contained lymph stream is merely seeking the course of least resistance all normal upward avenues for dramage being closed.

### COMMENT

For confirmation of the mass of evidence against any normal retrograde dissemination of neoplastic cells from malignant growths in the upper part of the rectum and above presented in the preceding pages, it is interesting to refer to the pathologic data which have thus far accumulated in the literature Table I represents a complete summary of such data.

In more than 239 of the 507 cases from the literature in which the removed tissues were completely examined nodal metastasis was observed to occur Of these only 8 gave evidence of an involved node below the level of the lesion itself As the lower level of the lesion was not defined in each case the actual dis tance of these nodes from the lesion can only be conjectured Nevertheless, in 7 of the 8 cases there was no spread below the 2 centi meter level which when interpreted in the terms outlined in this study remains insignifi cant. One case therefore that of Gilchrist and David in which the involved node was 4 centimeters below the lesion represents the total significant retrograde lymphatic flow from carcinoma of the rectum contained to date in the literature When combined with results given previously for our cases only a fraction over 1 per cent of far advanced malig nant growths of the pelvic colon may be ex pected to metastasize in a retrograde fashion If this obtains so rarely in cases in which the patient is already doomed to early demise because of the advanced nature of the lesion one may be justified in making the statement that retrograde lymphatic metastasis never occurs from growths still in the stage of reasonable

Perusal of Table I will further demonstrate that about a half of all neoplastic growths of the rectum when seen at operation do not as yet have nodal involvement. To be certain that this was true over the years from which the cases in this study were drawn Table III was constructed. There it will be noted that in 59 per cent of the cases there was no nodal involvement. To be sure had all these cases shown from 1916 to 1942 inclusive been subjected to intensive study no doubt the 59 per cent would drop below 50 per cent as recent published studies in which the data were so treated indicate (8 16) However the 1 per cent incidence of retrograde lymphatic spread in advanced cases when adjusted to include

NOMA OF THE UPPER PART OF THE RECTUM RECTOSIGNOID AND SIGNOID WINCH THE LESION WAS RESECTED AND GRADED (1916-1942 INCLUSIVE)

GRADED (1916-1942 INCLUSIVA)						
GRAD	ED (19			- 1	Grades (Bro	sed 4
	Tol	al l	(8,00)	jers)		
	١		27	Per cent	Number	Per cent
Nodes	Number	Percent	679	37	1	63
Positive	910	1	1, 60	1	17	1 35
Negative	195		1, 00	00	333	1
Total	2,906	1 00	ستتصل		occi)	na 1

the average type of carcinoma occurring in the rectum (approximatel) 50 per cent with nodes uninvolved) then drops to less than 0 5 per cent and as such becomes negligible Should it not be possible therefore in the light of pathologic evidence and in view of the many recent advances in colonic surgery to preserve the lower part of the rectum in a very considerable number of cases in which the patients heretofore have been deprived of normal sphincteric control (10)? Perhaps time alone will provide the answer but certain it is that such attempts are more than justified and should engage the attention of all surgeons who endeavor to relieve the encumbrances of rectal neoplasms.

# CONCLUSIONS

The following significant features deserve a

word of emphasis in conclusion r Because carcinoma of the rectum is primarily of a low grade of malignancy the disease tends to remain localized for a consid crable period and thus lends itself admirably to surgical attack

2 As carcinoma of the upper part of the rectum and the rectosigmoid has only one normal channel for lymphatic spread-upward-provided local growth by direct exten sion has not incorporated neighboring organs, it should be suitable for radical segmental resection with preservation of the rectal sphine ter and restoration of the normal continuity

3 Radical segmental resection implies the of the bowel removal of a wide section of bowel together with its complete node-hearing region just as the abdominal portion of a combined abdomi nopermeal resection is now performed (tech nique to be reported)

- 4. Section of the bowel must be at least 2 centimeters below the lower palpable edge of the lesion to satisfy pathologic regulre ments. The technical requirements in the successful performance of an adequate anastomosis in this area also involve the removal of such an amount of tissue because of the size and position of neoplasms so located.
- 5 It has been demonstrated that even in far advanced cases of carcinoma in this region. retrograde spread along the course of the bowel occurs to any degree in only i per cent.
- 6 When such retrograde spread can be demonstrated it is an indication that upward normal channels have been blocked. 7 When these facts become more generally
- appreciated and the technical procedures required for such surgery are subjected to refinement many sufferers from neoplastic lesions in the rectosigmoid region will enjoy a normal postoperative existence without the psychologic-to say nothing of the anatomic detriments of a permanent artificial anus.

# RECTAL STRICTURES DUE TO LYMPHOGRANULOMA VENEREUM

# With Especial Reference to Pauchet's Excision Operation

LOUIS T WRIGHT MD F.A.C.S., BENJAMIN N BERG MD F.A.C.S JOEL V BOLDEN M.D., and W ADRIAN FREEMAN M.D. New York, New York involving the labla majora and minora extending

ESPITE the abundant and ever in creasing literature on the general subject of lymphogranuloma ven ereum surgeons still differ greatly in their opinions as to the best method of treatment of lymphogranulomatous strictures of the rectum The use of sulfonamides and more recently of penicillin has lessened sec ondary infection in these cases, but in no way has it decreased in certain cases the tendency of the disease to progress and develop fibrous tissue that cicatrizes and produces marked

An example of such a patient is presented rectal stenosis. through the courtesy of Dr Marshall E Ross, of the gynecological service with whom one of us (L T W) examined the patient in consultation

S D colored widow 45 years of age a domestic, was seen August 7 1937 She complained of a swelling about the vulva, which began as a small plimple 18 years before, gradually grew larger and was painless. In 1935 because of constipation and pain on defecation she was treated elsewhere with deep The vulval swelling immediately increased in size she had lost weight, was easily fatigued and had pain in the perincum. The Frei x ray therapy test was strongly positive and a biopsy of tissue from the vulval swelling which also involved the anus showed marked fibrosis with round cell infitration and some plasma cells Examination on con sultation in August, 1937 revealed elephantiasis of the vulva involving the anus, a stricture of the vagina, a rectovaginal fistula and a marked annular stricture of the rectum I centimeter above the inter nal sphincter She was advised to have a coloatomy operation but refused. She subsequently moved to Connecticut, and in reply to a follow-up letter her physician wrote under date of November 28 1938 as

when first examined she had large aloughing pedunculated granulomatous ulcerated overgrowths From the Surpical Service of the Harlem Hospital, Dr Louis

P rora to surpeus

T Wight, director

Founders, lecture. Medicochirurgical Society of the District of Columbia, November 5, 945

from the publs in front and including the rectal sphincter behind. The rectal sphincter had been entirely destroyed and the septum between the vagina and the lower rectum was destroyed

a complete excision of the growth from the pubes to the coccyx was done and the wound was closed except for drainage at the angles. For about 2 weeks she did very well and then the wound broke open somewhat leaving a granulating surface, which was skin grafted The skin graft took for the most part. She left the hospital and was up and around

But the wound gradually broke down and signs leeling fairly comfortable. of intestinal obstruction developed Stricture ever narrowing could be felt at the junction of the rectum and sigmoid. As it seemed evident that the infection still persisted in the lower rectum and around the stricture and in the pelvis where a large mass could be felt it was decided to do a isparatomy At laparobe left it was uctified to to a lapse tomy a large dermold growth of the right ovary the size of a grapefruit was found. This growth was removed and in addition a hysterectomy double sal pingo-oophorectomy and colostomy were done bring ing the sigmoid out through a stab wound in the left flank. A resection of the lower segment of the sig moid and rectum including the stricture was also The patient withstood the ordeal remark ably well. She recovered and went home. Later she returned and at that time she had developed squam ous cell carcinoms at the left edge of the vagina at the junction of the vaginal mucosa and skin Ra dium needles were inserted in this growth and the and again she returned to cancer disappeared

She returned in a few weeks with a crater about 2 inches deep burrowing into the left upper leg her bome. toward the femoral artery and the left side of the vagina was involved in this crater sinuses discharged pus which oozed from openings throughout the floor of the crater so that as it was impossible to incise all these to give adequate drainage, the whole crater was congulated. When the alough was removed the crater looked quite healthy and was healing satisfactorily but the patient became increasingly than and emaclated and died. Autopsy was refused so the real cause of death

was not determined although it would seem that it was probably caused by urinary involvement from extension up along the ureters.

"The Frei antigen was continued here for some time and in addition two courses of sulfault ambie and antisyphilitic therapy for weeks were given. Before I saw her deep x ray therapy had been applied to the lexion. It was my opinion that the lexion might be cured by wide excision of the affected area and this is still my opinion. It was my belief that operation had been radiant enough but apparently some of the disease was left behind and gradually progressed."

This case illustrates the progressive nature of the disease its seriousness, the later devel opment of carcinoms with a fatal termination despite all known methods of treatment, including an abdominoperineal resection which here was obviously performed too late to be of value.

### HISTORICAL REVIEW

It seemed worth while therefore to review briefly the historical background of the disease and excision procedures and to report 26 per sonal cases in which we have resected the rectum preserving the anal sphilacter

Lymphogranuloma venereum was isolated in 1913 as a separate clinical entity by Nicholas, Favre and Durand. Frei (6) greatly advanced interest in the disease when he introduced his intradermal diagnostic text which has proved to be specific. Hellerstrom showed that lymphogranuloma venereum was due to a filterable virus. Frei and Koppel (8) and Bensaude and Lambling proved that the majority of non neoplastic strictures of the rectum were due to this disease.

Larsen in 1840 described inflammatory strictures of the rectum in 11 women

The first case of excision of the rectum for stricture was reported in 1864 by Glaser His patient had a recurrence and a years later he had to make a colostomy During the next 20 years several surgeons reported a few additional cases but because the operation was difficult and there were recurrences, the operation was discarded

To Professor Henri Hartmann (10) of Paris, goes the credit for recognizing the seriousness of the disease and giving it careful and prolonged study in all of its surgical aspects. Early in his career Hartmann per formed 16 external rectotomy operations. In ocase did it cure the patient, but it relieved

them, and all of them continued to suppose and suffer a certain degree of incontinence For this reason he gave up the operation Later in 1801 Hartmann and Ouent (11) re ported a series of as cases, most of them then own in which an excision of the stricture was done they concluded that the operation of excusion seemed to tend toward ultimate Since then for a period of annummately 40 years. Hartmann has advocated resection and has successfully performed the operation in many strictures of the rectum Careful histographological studies were made of each resected specimen. In 1020 he reported excision operations then 66 naticals for rectal stricture. An abdominonerined amputation was made in 6 cases and 104tients died a mortality of so per cent. At first the perincal amoutation was made without considering the sphincters and in 50 cases the results were only fair. One of a such patients died Only a patients could be followed and 2 of them were cured. The best results were made by intrasphincteric amputation, and he stated Real cures can be obtained in most strictures not accompanied by profuse Among 27 such amoutations smoouration there were only a deaths, and he states

It was possible to follow at of the patients. There was a recurrence of the stenosis in a cases and a colostomy was necessary in 1 year 4 years, and 6 years after amputation. Eight patients were inproved but continued to suppurate and one of these died at the end of 13 years with diarrhea and sweling of the face, probably due to amyloid degeneration. Twenty patients were cuted of their recibis and there was no stenosis or separation of the macosa An endoscopic examination of the rectum showed that the mucosa was normal in appearance. All of these patients were continent, but the continence was not absolute and when they had durnies they were not able completely to retain their fees Two of the patients complained of having moisture around the anua.

In Hartmann's Chiractic de Rection published in 1931 he has an extensive chapter entitled Rectifies Stenosantes which includes his experiences and many detailed case histories, and he concludes

"The first thing, in contradiction with the reconstructed opinion, is that excession of the rectal states may give complete and definite recovery characteristics indicated from the first, when the recitis

is abundant with suppuration and complicated with multiple fistulas amelionates the state of the patient considerably and makes life bearable. It may be wholly insufficient if the suppuration continues abundantly and above all if hemorrhages take place.

In 1926 De Roche reported 21 cases of fibrous strictures of the rectum in which resection was done with one operative death. Follow up results were obtained in 8 cases which were as follows after 1 year 1 suppurated, 1 had to be dilated 3 had relapsed and 2 had maintained excellent results

Dimitriu and Stoia in 1933 reported 25 cases of abdominoendoanal excision with preservation of the sphincter mechanism. Nineteen patients were cured 3 died and 3 recurred.

It seems that French surgeons were the first to recognize the essential need for surgical treatment of serious strictures of this type. The surgical treatment aimed at (1) correction of the stenosis, and (2) extirpation of all diseased tissue to prevent spread

Lockhart Mummery who represents the best English opinion in his textbook in 1934

If a stricture is noted near the anus very excel lent results in suitable cases are obtained. A modification of Whitehead s operation is all that is necessary to get rid of the stricture. It is not easy as a fibrous tissue outside the stricture prevents the separation of the mucosal membrane in the normal manner and this renders it difficult. When the stricture is more than one inch from the anus, the method is not possible and a formal excision similar to that for malignant disease is necessary. The operation of excision of a portion of the rectum for nonmalignant stricture is not one to be lightly undertaken, as a stricture serious enough to warrant removal of this portion is almost certain to be associated with a dense amount of fibrous tissue in the surrounding parts, which makes the anatomy quite abnormal, and may cause great difficulty in separation of the rectum.

In none of his published works has Lockhart Mummery shown any enthusiasm for the excision operation as a method of treatment for rectal strictures.

Martin, in 1933 reported a senes of 227 rectal strictures in negro women and concluded that the disease is incurable and tends toward an inevitable fatal termination, but nowhere does be suggest a definite method of

treatment. Spiesman Levy, and Brotman in a study of 183 strictures from the Cook County Hospital reported 2 resections one done by Davison and one by McNealy

Edwards and Kindell reported satisfactory results in 6 cases in which they made a preliminary colostomy and later did a perineal extirpation of the diseased rectum according to the technique described by Lockhart Mummery for rectal malignancy

Barber and Murphy from Bellevue Hospital reported 35 cases of resection 4 were one stage sacroperineal and 31 were abdominal colostomies followed by sacroperineal resections. Five of their 35 patients died, which gave a hospital mortality of 14 3 per cent. These 5 were extreme cases and there were no immediate postoperative deaths. They stated that in 2 patients who had had an original colostomy the colostomy ceased to function after the granulomatous process crept up to and involved the sigmoidostomy stoma. They made a permanent abdominal anus in their advanced cases. Two cases showed carcinoma

Woods and Hanlon in 1944, reported from the Cincinnati General Hospital 35 cases treated by rectosigmoid resection. In analyz ing 102 cases of rectal stricture they stated that 'colostomy has been usually employed at an advanced stage with no constant success They performed in arresting the disease. colostomy without resection in 34 cases 2 died of postoperative complications radical resection was performed in 35 cases. With no operative deaths, abdominoperineal resection was performed 23 times with good results in 20 of the 23 cases. In the perineal resection of the Lockhart Mummery type in 9 cases the results were good in 5 poor in 2 and fair in 2 They emphasize, however that the resection operation is a procedure of considerable magnitude and should be undertaken only after conservative methods fail. They con clude though, that the abdominopermeal resection is a satisfactory operation and that they have never seen resolution of firm fibrous strictures.

From the above résumé and from a study of other available literature, it becomes apparent that the general attitude in this country and in England up until about 5 years ago was that these cases were best treated by dilata ton if the lesion was apparently mild, and by a permanent colostomy if the patient's condition was at all senous. Only in the reports from the Beltumore Ctty Hospital by Edwards and Kindell from the Bellevue Hospital by Barber and Murphy and from the Cincinnati General Hospital by Woods and Hanlon have American surgeons shown any indication of their appreciation of the definitive treatment of this senous malady

Our own expenence coincides with that of Hartmann, namely that drugs dilatation and other simple procedures can in no way take the place of radical surgery in the treat ment of advanced rectal strictures. The increased tendency on the part of some American surgeons to use excision as an operation of choice indicates their recognition of this fact.

At Harlem Hospital we have had 4 deaths following dilatation of rectal stricture while Woods and Hanlon report 7 deaths following the same procedure at the Cincinnati General Hospital. There is no doubt that many deaths as a result of bougle or instrumental dilatation of benign strictures of the rectum have occurred throughout the country but the cause of death has not been so reported

Liccione was the first to report carcinoma as a sequela of rectal structure he recorded 2 cases. Woods and Hanlon reported 3 cases, and 3 cases were reported by Barber and Murphy from the Bellevue Hospital. We found records of 3 cases in the hospital and one of us (L. T. W.) observed another case in private. It is noteworthy therefore that the incidence of a superimposed carcinoma of the rectum upon this apparently benign lesion occurs much more frequently than is supposed.

We have used, in the treatment of these strictures every form of mild treatment excepting x ray and this includes finger dilata then dilatation with Wales beigges, posterior proctotomy in some instances, in rare cases Keller's tunnel grafts sulfonamides, Frei antigen dathermy carbon dioxide anow none of these availed but little in the serious cases. We have found that posterior proctotomy operations, followed by bouginage, give temporary relief but that in the final analysis thy serve only to spread the disease

and to make the stricture more rigid. Levy Holder and Bullows, from our out-patient department, reported good results with sodims sulfamilyi sulfamilate but the end-results have not been up to expectations in fact, some of the patients so treated are still coming back to the clinic and no doubt others have windered off to other hospitals.

Many of the unconsidered factors in the difficulties of the palllative methods of treatment of strictures particularly in colored people are due probably to the fact that or tain fibrous these reactions such as heides and elephantiasis, are predominant in colored races. Rosser used this observation to explain the frequency of rectal strictures in engone and postulated that they had a tendency toward fibroblastic tissue hypertrophy. This

has been our experience. Colostomy has been the ultimate procedure used in most clinics when the patient s life is obviously threatened Many colostomies have been performed by us for relief of benign rectal strictures in females. Seven patients entered the hospital with colostomies done chewhere 5 patients showed a stricture of the colostomy opening after operation 4 patients needed another colostomy Some authors have claimed that colostomy alone tended to cure or soften the strictures. This is, of course, absurd. It is true that ulceration, secondary infection and toxemia resulting therefron have been lessened by diversion of the feed stream but we have never found that colortomy cured a real fibrous stricture of the

rectum Experienced surgeons know that colostony per se is not without certain specific dangers This is true even when performed by surgeons of ability and great experience. These dangers are first, stenosis or a stricture of the colostomy opening Such stricture occurs a few months or a few years after the artificial anus has been made. It happened in 5 of our cases and in 2 patients admitted from other hopitals The second danger is retrograde or antenorgrade hermation of the bowel. This her niation occurs when the opening m the abdominal wall is too large If the proximal segment of the bowel is mobile an antenor grade herniation occurs. This occurred in 4 of

453

our cases If the distal end of the sigmoid is mobile a retrograde herniation occurs this happened in 3 of our cases and in 2 patients admitted from other hospitals. It is impos sible to foretell whether any of the above compheations will or will not occur following a colostomy We have seen secondary opera tions performed and deaths occur because of all of the above complications Therefore, it is our conclusion that colostomy although successful in some instances, 15 not and cannot be the best surgical answer to this problem. At best, it can serve only as a definitive method of treatment when no other rational option is available Aside from the surgical complications many patients will go on to their deaths and refuse help rather than have an artificial anus, and particularly is this true in young women in the early decades of life. It is likewise true that when the disease in volves the entire rectum or extends up to the agmoid, one has no choice but to advise a permanent colostomy with or without a sacroperineal resection otherwise the patient unquestionably dies.

We have seen patients with dangerous and serious sequelae which followed colostomy operations, even in the hands of experts. When there was marked stenosis of the colostomy opening-and these cases are numerous in colored people-we have had to perform another colostomy in the transverse colon Many strictured colostomy openings develop abscesses and fistulas. We have also had to treat some of the so called permeal resections done at other hospitals for serious late infection, which in one instance, extended up to the fifth dorsal vertebra (Figs 1 and 2)

The seriousness of this disease is further emphasized by Kassebohm and Schreiber who have reported from the Obstetrical Service of Harlem Hospital deaths due to the rupture of the rectum during spontaneous delivery and instrumental delivery and they consider it a very senous complication of pregnancy in fact, they recommend either therapeutic abortion if recognized early or

We agree totally with Hartmann that the cesarean section if late. treatment of choice of low strictures of the rectum is excision. We further believe that as

our technique improves the mortality will become lower It is also our opinion that sur geons in clinics who see large numbers of these cases will eventually come to this con

CASE REPORTS

The first patient was seen and operated on clusion in private by one of us (LTW) A brief ab-

stract of her history follows C M colored female, married, 34 years of age mother of one child 12 years of age was first seen in the office in November 1924 at which time she complained of an abscess near the rectum She was compained of an assess near the rectum She was emiclated, anemic, nervous, and weak. The only other essential point in her history was that she had had a history of having 7 operations for perrectal had a history of having 7 operations Constitution, deformed stools and at times passage of blood and nucus from the rectum completed her history Ex amination revealed a stricture of the rectum which would barely admit a No 24 F catheter Two figu lous openings were present on the right side of the rectum The perineum showed perianal and peri proctitic thickening in December, 1924, posterior procure unexcuing in December, 1924, posterior proctotomy with wide excision of all fistulous tracts was done. In October 1925 left inguinal colostomy was performed In January 1926, the rectum was excised preserving the external sphincter mechanism according to the method of Victor Pauchet. Conva lescence was slow but uneventful and complete healing of the perineal wound did not occur for a period of 2 months. This patient frankly stated that she would prefer to die rather than have a perma nent artificial anus and that she would willingly undergo any risk that would offer her a chance of health. Later the colostomy was closed. In the apring of 1945 19 years after her original resection this patient reported that she was in excellent health.

This first patient, with several others was demonstrated at a symposium given in 1938 by the surgical department of our hospital in honor of Dr Wilhelm Frei. Because of the satisfactory result in this case we were stimu lated to use the method beginning in 1931 on the surgical service of Harlem Hospital, and the authors of this article constituted an in door group for the clinical study of these cases. All of the second stage operations were performed wholly or in part by the senior

We have used this operation in 26 cases author (L. T W) The following is an illustrative case referred to

J G colored woman 26 years of age married 5 the senior author years, never pregnant, husband living and well.

History of rectal bleeding, pain during defecation with a ducharge of pus and mucus from the rectum which a discretize of possion much from the rectum during the past 4 years. She had been hospitalized caring the past 4 years one had been nonpressured on two or three occasions for dilatation of the stric on two or tures occasions for quantum of the stricture without much permanent relief. She had been ture without much permanent retter one nau been having chills and fever off and on for the Past 2 naving count and sever on and on for the past a years. Physical examination revealed a tight annu years. Paymens examination revenues a tigot annu-lar stricture of the rectum one half lach above the as stricture or the section one man men above the same which did not admit the tip of the little finger anus waxes use not assume the up or the fittee unger.
The blood count showed 4,000,000 red blood cells, And show counts answer a, occopion reu mond cents, 8 coo leucocytes, 74 Per cent polymorphomedean a oor sencestra, 74 per cent payment productions and per cent lymphocytes 55 per cent hemoglobia. so per cent symphocytes 55 per cent nemogioun. The Frei tent was strongly positive. Urinalysis showed occasional white blood cells and red blood anowed occasions; white smoot cens and ten successions 1.2 lives nitrocein nicou communy creatining 17 urea muto-gen 13 augus 75 Wassermann test negative. Colosgen 13 sugar 75 Vassermann test tressure: Conce-tomy was performed May 11 1936 (Fig. 3) She was discharged May 31 1936

She returned on October 5 1936 for the accord or excision stage of operation, which was performed or extensos stage or operation, which was performed on October 6 Pathological report by Dr. Solomon on October of Establishment reports by 5 by 5 centil meters. The mass had an irregular modular surface, with moderate hemorrhagic discoloration of the with moderate nemorrhagic unconstation of the surface. The mass itself showed marked fatty infisurface, the mean fiber shower market lately lumi-tration and on cut surface had a grayish white phone appearance and extremely firm consistency nurous appearance and extremely urn consistency Microscopic diagnosis acute and chronic inflamnation of the rectum with fibrosis. She was discharged on December 6 1936. On March 1 1937 she returned for closure of the colosiomy and was discharged May 32 1937 Figure 4 shows the con dition at the time of her discharge. In reply to a ention at the time of the referring physician wrote on December 14 1043 as follows

I cramined Mrs. G in 1043 for some other consymptoms what soever Examination bowed a
somewhat Patulous but perfectly competent anua.
At the end of the examining finger creatily there
striction. The patient weighed 35 pounds more than
the did in 1936, and she felt vory well.

Examination in our follow-up clinic in February 1044: was as follows no trouble with the rectum control of the follows no trouble with the rectum control of her bowel, for examination she showed as to linear scar in the suprapulation she showed as the following the suprapulation from his forection y operation with such that he had no September 144, 1043 for fibroid uterus. The do no September 144 and 144 are the following the fibroid uterus. The day around the There was no stricture or uteration.

In the 26 cases, in which the above procure was carried out, 2 deaths occurred in the hospital One death occurred on the day to appreciate the fact the patient was in secondary shock and needed a translusion. Another patient died of pentonitis following cleaure of the colostomy by one of the asso-

ciate surgeons on the staff death, of counce, was not attributable to the excusion operation. We have been able to follow 12 patients, 7 to 19 years after operation and the result in 8 19 years actual actory One patient still had sinuses on each side of the rectum which inter mittentis drained a slight amount of pur thr patient showed oaseous involvement and was reported as such (28) showed a slight tendency toward rectal prolapse where the mucosa had separated from Another nations the skin margin. One patient showed a ste nosis at the anal margin. One patient became psychotic. It is of interest to note that in all of these patients, excepting the one with the draining sinuses the disease was completely eradicated also that 8 of these patients had an excellently functioning anus with control over their bowels except when they took hustire.

TECHNIOUE The operation was performed in three stages in 24 of the 26 cases. The following drawings Figures 5 6 7 8 9 10 and 11 which are after Pauchet, and No. 12 which is diagrammatic-illustrate various steps in the operation. The first stage is the making of . temporary colostomy After the colostom and when the general condition of the patient has improved to the point where it is felt that she can withstand a resection, an effort is then made to disinfect the distal argumed and rectum in so far as possible as a preliminary to resection of the rectum. The second stage is the stage of resection and after this has healed, the third stage is to close the colortomy The time interval between the different stages varies according to the clinical condition of the patient.

to Early in our studies we used barnine earns to determine the length and extent of the strictured area, but we soon found that its reward was more a disadvantage than an advantage, the reason being that, although the procedure of the stricture the barnin often became inspirated above the stricture and was extremely difficult to remove. We later learned to investigate the extent of the stricture when the abdomen was open while we were performing the colosiony. Before any operation is

Fig. 1 Patient C. A. Appearance on admission November 10, 1036, of an abdominoperineal resceition of a stricture performed at another hospital o months previously on junc 3, 1038. Sie was emacated weak, and dehydrated The infection had burrowed upward along the supraspinous Beament to the level of the fifth dorsal vertebra.

undertaken we take great pains to explain to patients that they may have to go through life with a permanent artificial anus in the event we should find at the time of the colostomy operation that the stricture extends so high that it is not resectable. This the patient understands thoroughly beforehand and agrees to and it is also understood that if the stricture is one that will lend itself to resection that will be done and that eventually the colostomy opening will be closed.

Fig. 3. Photograph of temporary colostomy Patient J. C. May 31 936.

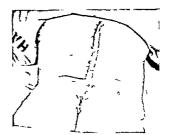

Fig 2 Patient C A Appearance at time of duscharge March 939. The entire area of infection was opened widely and packed with zine peroxide, which resulted in healing.

Two low strictures were resected in a one stage operation without colostomies having been previously performed (Figs. 13 and 14). In these 2 cases it was possible to resect the rectum without entering the peritoneal cavity and the healthy rectum was brought down intrasphincterically and sutured to the sur rounding skin. The only trouble with this procedure and for that reason we gave it up is the fact that although it cures the patients of their disease and their stricture it also brings the cervix of the uterus down to the vaginal introitus, and to this condition the patients later objected strenuously

In performing a colostomy for stricture of the rectum the sigmoid and rectum are examined carefully as to the length of the stricture the extent of infiltration of the disease and a search is made for enlarged lymph nodes this information is used as a basis for deciding for or against resection. In a few

cases not included in this series, the surmoid

was found to be plastered down to the poste

rior abdominal wall and the rectum and my

mold exhibited thickening of their walls and

luminal narrowing which rendered them

obviously unsuitable for reaction. In one patient, not included in this series, following resection the new anus cicatrized to such a point that we were not able to close the colostomy. This patient refused further treatment because also was satisfied with the colostomy. There is however no evidence of active disease around the rectum. In a large number of colostomies performed by as in

patient, not included in this series, following resection the new anus cicatrized to such point that we were not able to close the colostomy. This patient refused further test that the colostomy is a statisfied with the colostomy. There is however no evidence of active disease around the rectum. In a large number of colostomies performed by us in this disease we have searched carefully for line and other glandular enlargement this se have never found. For anemia at first used ventriculin with iron which helped to overcome the anemia rapidly. All of these patients gave a positive Wassermann reaction. In general, these patients at the time of the Internal time colostomy were usually emic.

In general these patients at the time of the preliminary colostomy were usually emanated tonic, and in very poor general chief condition. They were allowed to go bore until their clinical condition improved, which was 3 or more months, after which they were brought back for the second stage of the operation which was the excision of the return with preservation of the sphincter. After the latter stage which required usually from 4 to 8 weeks to heal the patients were allowed to go home for a few weeks, if they so desired,

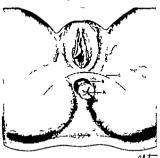

Fig. 7. A Button of skin around anus. B Sphincter and muscle exposed following dissection of anal mucous membrance. C Line of curvilinear incision (drawing after Parchet)

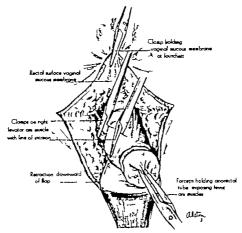

Fig. 8. The lower flap contains the sphincter and muscle (drawing after Pauchet)

after which they would return to have the colostomy closed. It should be pointed out that these patients because of their poor clinical condition before the colostomy and because of the magnitude of the second or excision stage require a longer period of bospitalization than do most patients and during this time they require careful supportive treatment.

The technique used was not original with us, but we followed in the main the one described by Pauchet Preliminary to the resection stage of the operation it was our custom at first to instill thrice daily 2 ounces of a to per cent solution of argyrol into the distal segment so as to render it as bacteria free as possible later we irrigated the rectum through the colostomy opening with a 1 5000 solution of zerohiran Ether anesthesia was used

The anal sphincter is dilated fully the anus is closed with a heavy silk suture and an area of skin about the size of a silver dollar is dissected up exposing the external sphincter

muscle The mucous membrane lining the anal canal is freed with scissors and blunt dissection just as in the Whitehead operation for hemorrhoids. The stricture is usually located at the junction of the rectum and the internal opening of the anal canal A curvi linear incision is made that extends from near the tuberosity of the ischium on one side upward to the fourchette and then downward to the area over the tuberosity of the ischium on the other side. The anterior wall of the rectum is then separated from the posterior wall of the vagina At times the rectum is unavoidably opened at this point, but where this has happened no serious infection has developed

The levator ani muscles on each side are divided between clamps close to the rectum and ligated. At this time one cuts through much scar tissue which bleeds and oozes very freely this hemorrhage is controlled by the frequent use of hot pads. After a partial dissection of the stricture from its surrounding

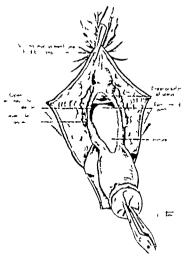

Fig. 6. Th. pouch of Dougla h. been opened (dra. g. after Lauchet)

tissues the apron of skin which carries in it the phincter muscles is allowed to fall forward and downward. The firm rectoeoccygeal ligaments are divided and retractors hold the skin flap downward. The rectum is then easily freed in the hollow of the sacrum and its lateral fascial attachments above the levator and muscles are divided.

The peritoneal cavity is entered through the pouch of Douglas. The rectum is pulled down to a point above the strictured area. The superior hemorrhoidal vessel and all other bleeding points are carefully ligated. The diseased portion of the rectum is excised at a point through healthy rectal tissue. The proximal end of the rectum is brought down intrasphincterically and its margins are su tured to the skin edges with interrupted black.

silk sutures which bring the rectal mucos membrane in direct contact with the sin Two I enrose or eigerette drains are placed into the peritoneal cavity one coming out at the lower angle of the wound on each side at shown in the illustration (Fig. 11). Yield of viseline gaure is placed in the new anal cand

The patient is given a blood translusion, go cubic centimeters of blood immediately after the operation and she is watched very closely during the next 4 hours for the possible during the steel possible of the possible of

### **OBSERVATIONS**

In performing the preliminary colostomy it is important to use the segment of sigmoid

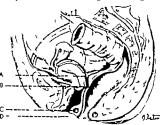

Fig. 12 Diagrammatic cross-section few at end of operation A Cut edge of peritoneum. B Rectum C Sphincter and muscle D Suture approximating mucous neembrane to skin.

Fig. 3. Patient H. F. Photograph of Introfun of patices 4 sho had some tage resection 4 years previously A. The cervix at the opening of the vaginal canal. This patient became perganat and was delivered by ceasuran section, year after resection of the rectum. Thirteen years later this patient has a well functioning arms but her cervix is still at the introfuse hich condition she has refused to have corrected.

that is at the highest point above its mobile part. This step will permit the segment to be drawn down when the rectum is resected. In one instance this point was not observed when a colostomy was performed and, during the resection stage of the operation, after the rectum was freed and the diseased porton excised, there was not sufficient mobility to permit the bringing down of the healthy end of the rectum to the skin This patient developed a psychosis upon learning that she would have to keep her artificial anus and she was transferred to a mental matitution where she died. It is imperative that the highest mobile point of the sigmoid be the site of choice for the performance of a preliminary colostomy if the stricture is resectable. If the stricture is not resectable the making of a colostomy at that site for a permanent artificial and B dangerous because there may be the development, later of a retrograde herniation in a few cases.

With the advent of the sulfonamides, particularly sulfasuxadine which has been a boo in lessening infection in the large bowel, it is possible that we may be able to do their sections in one stage and open the pentional cavity without danger. This we have not retarmpted. We still believe that the three

Fig. 16 Patient M B. Anal tumor, stricture of rectum, and fibroid of uterus. Colostomy and hysterectomy May 14, 1932. Reacetion of tumor with stricture by dividing lower third of vagins and sphincter muscles. Closure of colostomy October 8, 1932. Follow-up 12 years later showed good regults.

stage operation of preliminary colostomy fol lowed by resection when the clinical condition of the patient has improved and followed by the closing of the colostomy is the procedure which gives the patient the greatest protection

Sometimes these patients present tumor masses around the anus which have to be excused at the time of the second operation Figures 16 and 17 show the external appear ance in 2 cases in which resection was done and the end results were excellent.

Dr Milton J Schreiber from the obstetrical service reports that he has delivered sponta neously 4 of the patients who have had excision operations in this series without any ill effects

We have had no experience with Hart mann's method of penneal resection the Lockhart Mummery method of resection as used by Edwards and Kindell and Barber and Murphy and the modification as used by Woods and Hanlon In all of our cases we have preserved the sphincter a point which Hartmann later conceded to be important although his operative approach was sacral rather than the approach which was used by Pauchet.

Fig 17 Patient V B Anal condition at time of admission in 1934. Three stage operation. Well functioning anusin 1945 at which time she was on the gynecological service for a pelvic mass. No signs of anorectal disease.

It should be clearly understood that the operation of excision is a very serious operation and one to be used only in selected cases and by surgeons of experience. It should not be performed by the surgeon who does this type of operation only occasionally although we are certain that as a given surgeon soperative experience with the disease grows his results will improve. It is hoped that early diagnosis and the use of chemotherapy will obviate the necessity for the use of surgery in these cases before a true rectal cicatricial stepois has occurred.

### CONCLUSIONS

- I Resection of the rectum with excision of the diseased area and preservation of the sphincter is the treatment of choice in certain selected cases of fibrous stenotic strictures of the rectum.
- 2 Permanent colostomy may have to be performed as an operation of necessity when the disease is so extensive that it cannot be resected with ease
- 3 Abdominopenneal resection may be justified in certain cases in which the stricture extends so high that a sphincter preservation operation cannot be done
- 4 Twenty six cases in which resection of the rectum with preservation of the sphincter was performed according to Pauchet's tech inque are reported with 2 immediate deaths

inguinales

to. HARTY

and a later death. These 2 immediate deaths were preventable and cannot be ascribed to the operation her se but to our inexperience bollow up of 12 cases shows that the disease was cured in all but one and this one pre-ent fistulous openings which drain intermittently due to hone involvement

- s Pauchet's operation has proved a satis factors procedure in our hands an I is worths of further trial
- 6 Two very low strictures were resected in one stage and they resulted in complete cure 7 Early diagno 1 in our opinion fol

### lowed by an excisi n operation is the best treatment for tibrou - trictures of the rectum

# LIGATION OF THE INNOMINATE ARTERY FOR INNOMINATE ANEURYSM USING RUBBER BANDS

### Report of a Case

JOSIAH C TRENT M D F.A C.S., Ann Arbor Michigan

F the fewer than 100 operations per formed on the innominate artery since Valentine Mott's initial report in 1818 approximately 25 per cent have been for innominate aneurysm. Green ough in 1929 collected from the literature 91 ligations or attempted ligations of the innom inate artery only 17 were performed for aneurysm of this vessel and in only 13 was the artery actually tied In 1937 Rundle added 8 cases to Greenough s 13 (3 of these Greenough had listed as subclavian aneur vsm)1 and Brock in 1941 added another From these reports and including the present case it appears that the innominate artery has been ligated some 23 times for aneurysm

The relative infrequency of ligation of the innominate artery for aneury sm is understand able because of (i) the rarity of the condition (innominate aneurysm accounts for less than 3 per cent of the total), and (2) the high mortality of the operation (Table I). A successful case was not reported until 1911 by Sargent although Cuneo according to Guinard successfully ligated the innominate artery for aneurysm in 1905. Many more successful ligations have been performed during the past 25 years but the procedure remains hazardous with secondary hemorrhage still the chief cause of death (Table II).

Greenough gives a detailed description and analysis of the types of operations employed on the innominate artery including proximal or distal ligation or both ligation of the in nominate and subclavian or carotid vessels triple ligation of the innominate subclavian and carotid arteries triple ligation and excision of the sac and innominate carotid and excision of the sac and innominate carotid and

From the Department of Surgery Duke University Hospital, Durham, North Carolina.

Early reports of ligation of the innominat artery for aneuryum are frequently difficult to interpret because of the failure of the uthors t describe the exact location of the lesion

TIBLE I —MORTALITY IN 28 CASES OF OPER ATION ON THE INNOMINATE ARTERY FOR INNOMINATE ANEURYSM

	Ligation	Mortality	Attempted legation	Mortality
Greenough	13	6	4	4
Rundle	8	3	i	t
Brock	1	1	0	0
Trent	1	0	0	•

Total 23 10(43 5%) 5 5 T tal number of cases—28 Mortality--15 (53 5%)

vertebral ligation in which silk hemp ox aorta ox peritoneum kangaroo tendon car bolized catgut chromic catgut horsehair silver wire and many other materials were used as ligatures. He concludes that multiple ligation is advisable combinations including the subclavian surpass those with the carotid and the vertebral should not be included

After careful evaluation of the operative treatment of innominate ancurysm Rundle reaches similar conclusions (1) if an attempt is to be made to ligate the innominate trunk it is essential to split the sternum otherwise access is inadequate and the ligature may fail to occlude its lumen (2) Simple proximal ligation as a method of treatment is most un suitable while necessitating as thorough an exposure as the more complete operation it gives the poorest results and is too prone to be followed by cerebral vascular complications.

In any type of ligation of the innominate trunk there are two circulations to consider

TABLE II —CAUSES OF DEATH IN 15 CASES OF OPERATION ON THE INNOMINATE ARTERY FOR INNOMINATE ANEURYSM

the peripheral and the cerebral Greenough in 75 ligations found no cases of gangrene of the homolateral arm although there were several cases of atrophy There were 7 deaths from cerebral lesions some of which must be attributed to ischemia

Although the recommendations for surgical therapy outlined above are sound they are not always applicable a fact well illustrated by the following case which presents several un usual features namely (1) the approach to the innominate artery was through the chest rather than the sternum since it was feared that manipulation of the sternum or clavicle would result in the tearing of the wall of the aneurysm (2) rubber bands were used to ligate the vessel and (3) the aneurysm completely disappeared following proximal ligation of the innominate trunk

### CASE REPORT

R. W A 51137 52 year old colored male was first seen at the Duke Hospital November 11 1940 At that time he had a strongly positive blood serology and annal fluid A diagnosis of central nervous system syphilis was made and the patient referred to the local Department of Public Health where is received a course of antiluetic therapy

He returned to the clinic May 37 104, 18180 that 1 month prior to his whit a small host the size of a walnut had appeared suddenly at the bar of his neck on the right after a seven coupling sed The cough had continued and the knot had great rapidly in sure. He had no obstruction to his breathing but had noticed some houseness and dryshap into the complained also of throbbing headeness when the complained sho of throbbing headeness when the complained sho of throbbing headeness when the complained sho of throbbing headeness when the complained had not be synchronous with his heart beat.

seemed to be synchronous with an acceptable problem. Physical caramination revealed face peaks, a blood pressure of 148/110 in the right are as 14/700 in the left a heart slightly enlarged to the with an irregular rhythm due to dropped best, as a late disastole murmur over the aordic are, as above the clavicle and resting on it was a large plasting definitely expansion meaning against the problem of the property of the meaning again instally 10 by 18 by 7 centimeters (Fig. 1). The standed beyond the middle silbooth it was prominently on the right. The trackes was natice deviated to the left and laryupocopic canalation was unsuccessful. The size of the ancuryup problems.

ited anteflexion of the head.

Roentgenograms of the chest (Fig. 3) shored alight enlargement of the heart to the left with sent alort to still the chest of the tortunosity of the aorta but no definite agent) as of this vessel. A shadow in right supracardiac regas

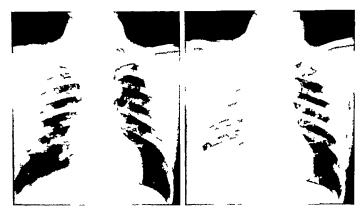

Fig. 2. a., Preoperative roentgenogram of the chest showing the shadow in the right supracardiac area characteristic of an enlarged innominate artery alight enlargement of the beart to the left and tortuouity of the acrts but no def

inite aneurysm of this vessel. The traches may be seen far to the left. b Seventeenth postoperative day Roentgenogram of the chest showing the elevated disparagm on the right.

was characteristic of an enlarged innominate artery The trachea was displaced considerably to the left.

A diagnosis of aneurysm of the innominate artery and possibly the right common carotid artery was made and the patient referred to the surgical clinic for consideration of ligation of the innominate artery

He was admitted to the surgical service on June 16 1944 stating that the mass in his neck had in creased in size since his last visit to the clinic. The physical findings were essentially unchanged over those last recorded except for a slight increase in the size of the aneurysm

The accessory clinical findings were as follows hemoglobin 13.4 grams (86%) red blood count 4 160 000 white blood count 6,360 blood Wasser mann reaction positive Kahn positive Kline and Mazzini tests negative Spinal fluid tests showed Wassermann reaction cocco colloidal mastic test oocooo Pandy negative cell count o

Fluoroscopy and films of the chest showed the changes described The electrocardlographic record was indicative of coronary artery disease.

A diagnosis was made of syphilitic aneutysm of the innominate artery syphilitic cardiovascular disease with cardiac enlargement and myocardial dam age from coronary involvement aortitis and dila tation of the aorta.

During the 9 days the patient remained in the hospital before operation the aneurysm increased visibly in size, and rupture appeared imminent. Therefore in spite of electrocardiographic evidence of coronary involvement and the attendant high operative mortality ligation was recommended A week before operation patient was given a cubic

centimeters of bismuth subsalicylate intramuscularly On June 24, 1944 with the patient supine and under pentothal and endotracheal 50 per cent ni trous oxide-oxygen anesthesia, a hockey-stick incl sion was made over the second rib anteriorly on the right extending vertically along the lateral border of the manubrum to the jugular notch. The under lying pectoral muscles were cut and the second rib exposed and resected as far laterally as possible The costal cartilage was rongeured away to the sternum care was taken not to injure the mammary vessels. The pleural cavity was entered through the rib bed In order to obtain better exposure the third rib was divided laterally and medially. The under surface of the aneurysm could be visualized readily and palpated at the apex of the pleural cavity. The pleura overlying the great vessels was divided and reflected back. The innominate veins and the su perfor vena cava were separated from the underlying arch of the aorts and the innominate artery and retracted exposing the greatly dilated innominate trunk which measured approximately 4 centimeters in diameter at its junction with the aorta. By careful manipulation and dissection a large goose neck clamp was passed under the vessel and a cotton tape placed around the artery (Fig 3) It was feared

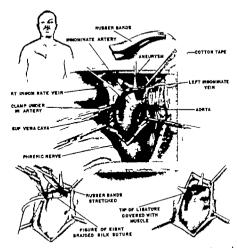

Fig. 3. The right chest was entered through a bockey stick Incideo over the second rib (left upper inset). The pleura overlying the great excels as a Incide, the 4th pushed back, it wells retracted, and the innominal sattery proped. Vegoes need lamp was passed behind the artery and two rubber band pulled through by serias of tage (central cut). The rubber hands or estretched and satured anteriorly using heavy braided slik (left lower inset). The ends were triumed and the prestuding bloic overed with musels (right lower baset).

that secondary hemorrhage might follow ligation of such a large thin wailed vessel with a narrow non classic ligature. Therefore two new rubber band

2 millimeters in width and 75 centimeters in length were obtained a sturred to the tape and drawn under the vessel. The bands were then pulled up very snugly sensel the bands were then pulled over the anterior of the bands were then pulled of the vessel and a sturred to retain a cochided there was immediate cereation of pulsation in the ancuryam and right superficial temporal artery and the blood pressure and pulse in the right arm could no longer be obtained. After the rubber bands had been trimmed, a small nubbin remained which hay immediately beneath the finon lants veins, and the possibility of erosion into these vessels had to be considered. To obviate this, a piece of muscle was sutured over the stiff protuding ends, to form a soft pud between the ligature and

vessels. The wound was then closed in automatical vers, with cost mouse chromic o Duker sturf for the pieura, interrupted double medium crotton for muscle and fissels and interrupted fine cotten for subcutaneous theuce and size Patients stood per action well and returned to ward in good coofficial.

Following the operation no scakees of the bala lateral arm or opposite side was noted. He bala fairly stormy course for the first 3 days due to the fourth day following penicillin and saintenance therapy his temperature returned to normal the fifteenth day small teodr fluctuats areas eveloped over the creet of the accorping. The sort yarm no longer pulsated but had not decreased a preciably in size. Application of the fluctuation are vielded pus and blood which control gram post tive occi. To forestall spentaneous rupture, a small incluon was made in the skin at the point of segments.

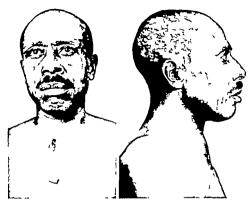

Fig. 4. Three weeks postoperative. Anterior and lateral views of the patient abowing almost complete disappearance of the mass. The opening of the small draining sinus can be seen just above and to the right of the jugular notch

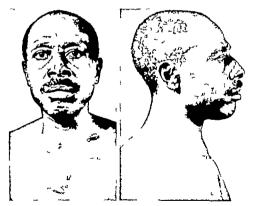

Fig 5 Six weeks postoperative. Anterior and lateral photographs show a further decrease in the size of the mass. The opening of the supraclavicula sinus tract! evident.

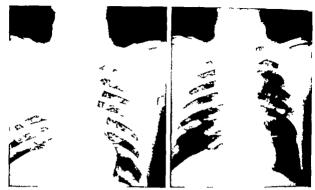

Fig 6 a, Roentgenogram of the hest made approximately 3½ months postoperatively showing prominent shadow over the right apex displacing the sortic arch t

the left b, Roentgenogram of the chert made 154 months after operation showing clearing of the right aper with residual mass in the region of the humania te artery

Fig. 7 Ten months postoperative. The mass has completely disappeared and the sinus tracts have healed. The outline of the right sternomastical muscle is clearly vis like. Subjectively the patient is well.

Fig. 8. a, Ten months postoperative. There is a large dense mass in the right supracardiac area at the site of the ligation. The traches is practically in the midline. The

diaphragm has descended b, A kymogram made of the chest reveals no pulsation of the mass which has been described in a.

tion and 100 cubic centimeters of pus, old blood and thrombus were expressed from the neck. No hemorrhage ensued Following this, the mass in the neck disappeared (Fig 4) Compresses were applied, the inflammation and induration subsided and healing occurred except for a small persistent sinus A chest plate on the seventeenth day showed the chest to be clear with the traches still slightly deviated to the left. The right duaphragm was ele vated and fixed from stretching of the phrenic nerve at operation (Fig ab) A slight pulse was felt in the right arm on the seventeenth day but the blood pressure could not be recorded. The blood pressure in the left arm was 118/76 Oscillometer studies of the right arm revealed a maximum of 2 units pulsa tion above the elbow. An electroencephalogram showed no depression of cerebral activity on the right. He was discharged on the twenty first day with instructions to continue his antiluctic therapy

On August 7 1044, the patient was readmitted to the hospital complaining of bleeding from the site at which the infected ancurysm had been drained (Fig 5) Physical examination and chest findings were

essentially as on discharge July 14, 1944. While in the hospital fairly brisk bleeding oc curred from the sinus with an estimated blood loss of goo to goo cuble centimeters. He was given a blood transitusion. A skiedan injection of the sinus tract revealed only a small pocket at the site of the aneur yam. It was felt that the hemorrhage probably had come from the versels communicating with the old

aneurysmal sac. An attempt was made to throm bose these vessels by injecting first a solution of 50 per cent glucose and later 5 per cent sodium mor rhuate into the tract. Following this no further hem orrhage occurred. The cavity decreased in size and the patient was discharged on August 22 1944.

On August 36 1044 the patient was readmitted complaining of a swelling under the old thoracotomy wound which later proved to be an abscess. It was feared at first, however that it might be due to further hemorrhage and since he was afebrile it was not incesed He was diskraged on August 27 1044.

On September 4, 1944, the patient was readmitted complaining of increase in the size of the aweiling under the old inclaion and further bleeding from the supraclavicular sinus tract. He had some fever and since there was some clouding of the right upper chest on x ray examination (Fig. 6a) it was decided to explore the mass. On September 7, 1944, the old thoracotomy wound was reopened and a large abscess cavity approximately 8 centimeters in diameter over the apex of the right lung was encountered and drained. The cavity contained a large quantity of thick pus from which nonhemolytic Staphylococcus aureus was cultured. The site at which the ligation had been done could not be visualized but it was possible that a small sinus at the bottom of the cavity communicated with it. The patient was discharged improved on September 11, 1944.

discharged improved on September 11 1944
On September 28 1944, the patient was read
mitted complaining of dyspnea, substernal oppres-

son and increasing hostociness but no further bleeding. Re-examination of the chest by xrsy revealed that the shadow in the right upper chest was still prominent with the placement of the aortic arch it the left it was felt that there might be a further accumulation of pus over the apex and n September 30, 1044 the oll wound was again explored. No pus was found. The patient improved and was decharged on November x tends.

On December 13 1944 the patient wa read mutted complaining I su liden one-to discrete cough ing which had persisted for 13 to 18 hours. If had coughed up 2 cut fulls of blood and had inoticed some bleeding from the emps ema drainage wognd. Bron

cho-coose examination was refused

Physical and xray xaminations (Fig. 6b) revealed some cleaning at the right apex. While in the hospital be coughed up only a small amount of blood tinged sputum. The exact source of his bleeding was unknown. He was rea used and lischarged on December 18, 1044.

On December 22 1044 he returned to the clinic complaining of coughing up blood. His condition wa good and his cough had topped. He was re-

a sured and sent home On January 31 1043 he wa again seen in the out

patient clinic with imilar complaints. All draining sinuses had healed. He was reasoured an I hischarged. On F bruary 12 1045 h returned to the out patient clinic tating that he ha! gotten slong well excent that he had coughed up a large quantity of

blood on a occasion. Ceneral condition the same On April 25 1045 essentis to month after proximal ligation of the innominat artery the patient receiving to the clinic for a check-up. He had been receiving weekly intramuscular injections of bismuth ubushies/lat since January 3 1045. It had no dispines but occasionally coughed up blood tringed puttin. He had no complaints other than diszanisa on I wering his best. He had excellent used further arm but, tasted that in cold seather rush

hand becam cold and till left hand not affected.

On xammati n the aneurysmal ma had completely lisappeared (Fig. 7). The mall sinu in this are a not the old thoracotomy wound had completely

healed. The anterior border of the right sternocleidomastoid muscle was again clearly visible. Th up nor media tinum was slightly widened to per cu ion on the right. The lungs were elear to auscul tati n. Pulsation in the right brachial and radial arteries were faintly perceptible. Pulsations in th. right common carotid and superficial temporal arteries were questionably felt. The blood pressure in the right arm could be heard faintly at 74/60 and 104/74 in the left Examination of the chest by fluoroscopy and Lymography (Fig. 8a b) revealed a large nonpulsating mass in the supracardiac area at the site of the ligation of the innominate artery This mass was interpreted as scar tis u and not as an aneurysmal dilatation. The traches had almost returned to the midline and the diaphragm had

descended and had regained 50 per cent of its motion

#### SUMMARY AND CONCLUSION

A case of syphilitic ancurvam of the innerinnte and common carotid arteries which for appeared after a severe couching spell by been presented. The aneuryam was leased proximally at its functure with the agets be the use of two wide rubber bands. Polisting ceased immediately following lightion although no appreciable decrease in the size of the miss was noted to weakness of the homolateral arm or opposite side was observed. On the fifteenth postoperative day the aneurym lecame fluctuant and was drained to avoid spontaneous runture. Approximately 100 rebic centimeters of our and thrombus were obtained without bemorrhage Follows drainage the mass subsided. Two and mehalf months later hemorrhage occurred from a nersistent sinus tract at the former site of designate. An attempt was made to through hose the feeding vessels by the injection of so per cent dextrose and s per cent soften morrhunte solutions Although these meaures appeared to be effective in stopping the hemorrhage other complications developed He returned a month later with an infection under the old thoracotoms wound which subaided following drainage Subsequently both the persistent supraclavicular sinus and thor acotomy wound healed with complete drappearance of the aneury sm There remains a residual nonpulsating mass at the ute of ligtion which is believed to be scarring resulting from the irritation of the rubber ligature Patient has occasional episodes of coughing productive of blood tinged sputum due perhaps to some involvement of the trached in the cleancial mass. Except for these enisodes the patient states that he feels as well as he ever he

I roximal ligation of a syphilitic anemysts of the innominate artery with rubber beads has resulted in complete disappearance of the aneurysm and clinical cure of the patient.

# FAILURE OF THE UROGENITAL UNION

# ALEC W BADENOCH M.A. M.D., Ch.M., F.R.C.S., Wing Commander R.A.F.V.R.

a fairly extensive search of the liter ature very little reference is found to a failure of union between the vasa effer failure of union between the epididymis entia of the testis and the epididymis Hobda\ mentions that in the horse the cpi didyrus is occasionally found in the inguinal canal while the testicle is in the abdomen Kaufman (1922) and Windholz (1926) men tion complete separation of the epididymis and tests, and Brunzema (1929) found this condition four times in 104 cases of undescended testis. Wilson (1939) records one case in which the testis was in the inguinal canal and the cpldidymis was in the scrotum Om bredanne (19 3) describes the separation as occurring occasionally when there is a vestigual testis and Wangensteen (1932) quotes a case of an epididymis with a vestigial structure attached to it which had none of the appear ance of a testicle

## UROGENITAL UNION

In a 21 millimeter embryo (7th to 8th week) the wolfnan body consists of about 26 tubules situated in the lumbar region and all in a process of degeneration This remnant of the mesonephros is divided into two portionsupper and lower The upper or epigenital part consists of 5 to 12 tubules the blind ends of which become surrounded by the epithelial nucleus, forming in the indifferent reproduc tive gland so that each comes to be in a sort of bay in that part of the nucleus from which the rete tests is formed From the beginning therefore the wolfhan collecting tubules and the tubules of the testicular rete are in intimate contact and he wall to wall The urogenital union takes place when the two open into each other (Fig 1) and this appears to occur at very different periods. Felix saw it first in a 60 millimeter embryo-head foot length

When union has taken place the collecting tubules are known as the vasa efferentia. In the 4th to 5th month they begin to coll at the end nearer the wolffian duct but remain

straight toward the testis. Later, they are surrounded by a firm connective tissue mem brane and become the coni vasculosi All of the 5 to 12 tubules do not necessarily take part in the union but if not, they frequently persist as remnants in the epididymis forming the vasa aberrantia One or two may unite

before joining the rete testis. The lower or paragenital portion of the wolf fian body consists of two or three small tubules closed at both ends and persists as the para didymis

# FAILURE OF UNION

In a series of 42 cases in which patients with incomplete descent of the testis, were operated upon I have seen 3 in which there was no macroscopical union of the testis and epi didymis. In 2 of these the absence of union was confirmed microscopically

Case 1 A wireless air gunner complained of pain in the right groin since beginning to wear parachute harners. On examination the right compartment of the scrotum was empty and he stated that the testis the activiting was empty and he stated that he testing had never been down. The right testide could be felt in the inguinal canal and pressure over it caused ten in the inguinar cause and pressure over it caused the pain of which he complained. The left testicle was well down in the scrotum and it and the epi didymis felt normal No evidence of hernis was noted October 13 1941 under nitrous oxide ges, oxygen and ether anesthesia pentothal induction, the right inguinal canal was opened and the testis was found lying in a patent funicular process, the fundamental states and the sac was opened the testis was seen lying on the floor about 1 inch from the internal abdominal ring (Fig 2) The sac was freed from the floor of the inguinal canal, and the epididymis was found with the globus major almost at the fundus of the processus and completely separated from the body of the testis. The vessels of the spermatic cord were very short and the testis epididymis, and sac were re On microscopic examination the testis showed the usual picture of an undescended organ. The seminiferous tubules were composed of a single layer of cells occasional spermatogonia were present but no spermatozoa. There was no microscopic con nection between the body of the testis and the epi didynis although there appeared to be one or two ducts leading from the upper pole of the testis. The termination of these ducts were not identified

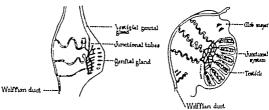

Fig. 1 A diagrammatic representation of the progenital union. (After Krith.)

Attended complaining of occasional swelling, with pain in the right groin for some 12 months. The right testicle had never been in the scrotum. A small oblique right inguinal hernia reaching to the external ring was found the right testicle was not felt. The left testicle was well down in the scrotum and it and the epididymis appeared normal On May 2 1012 under nitrous oxide gas oxygen and ether anesthesia pentothal induction, the right inguinal canal was opened. A small patent processus vaginalis was found. The testis was intra abdominal but the base of the mesorchium was just inside the inguinal canal (Fig. 3) and the testis could be brought into the canal. His attacks of pain may have been due to intermittent prolapse of the testis and strangulation of the cord. The was ran down the canal on the posterior wall of the sac and termi nated in a splayed-out epididymis which had no connection with the body of the testis. The was and epididymis could be brought well down, to reach the bottom of the scrotum, without difficulty but the testis could not on account of the shortness of the vessels of the spermatic cord. The testis enididymis and sac were removed. Microscopically, the picture was similar to that in Case 1

Inguinal ring

Testio

Vos defirens

Fig. s. Failure of descent of the right testis and failure of union with the epididymis.

CASE 3. Attended with a large left sided scrotal bernia which had gradually been increasing over a period of 10 years. The bernia was easily redecide but no testicle was felt after reduction. There was a suggestion of a thickened structure, in the posterior wall of the sac, in the empty scrotum, and a preoperative diagnosis of atrophy of the tests was made. On December 7 1941 under altrons onde gas, oxygen and ether anesthesia, pentotial infac tion, the left inguinal canal was opened. A large patent funicular process was found. When the sec was opened, the testis was seen lying on the for (Fig. 4) half an inch from the inguinal ring, and bound to the sac by adhesions. The vas passed days to the scrotum and terminated in a splayed out qu didymis. This had no macroscopic connection with the testis. The funicular process was divided prodmal to the latter and cleared from the cord and epdidymis. The testis was then easily mobilized and brought into the right scrotal compartment. The floor of the canal was repaired with a strip of faces

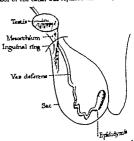

Fig. 3 An Intra-abdominal right testis and taker of union with the epididymis.

# BADENOCH FAILURE OF UROGENITAL

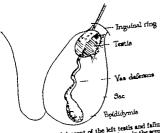

Fig. 4 Failure of descent of the left testis and failure of mion with the epidedymia which is well down in the scrottm.

taken from the aponeurosis of the external oblique

These 3 cases would undoubtedly appear to illustrate failure of the urogenital union Dur ing the past 3 years I have almost invariably included an examination of the testis on each male patient who has been referred to me I have not observed anything which would sug gest complete failure of union in a normally descended testis and it is probable that this occurs only in association with incomplete descent However I have been struck by the comparative frequency of the occurrence in young adults, of a small cyst in the region of the mediastinum testis, and believe that not infrequently this is due to a partial failure of the urogenital union

Ogier Ward (1922) reported 17 cases of spermatocele and described the etiology The youngest of these patients was 41 years and the average age was 55 years. He considers it as a disease of maturity and that a spermatocele is a retention cyat of unknown pathology Dorne (1926) reviews the literature on the subject and also considers that the condition is a retention cyst. Among the etiological factors, he mentions trauma, gonorrhea, or any previous inflammatory process Rolnick (1928) in the routine examination of 55 000 men for spermatocele found a clinical incidence of 1 per cent. He operated on 12 patients and found that it was possible to dissect out the cyst in only one case which was shown to have been formed from a distended tubule. He attempted to produce true spermatocele

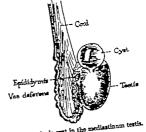

Fig. 5 A single cyst in the mediastinum testis.

in 28 dogs and failed in each case. McCrea (1935) gives the following classification of cysts in relation to the epididymis (a) cystic disease of the epididymis (b) cysts developing between the testis and the head of the epi didymis, (c) cysts of vestigual structures near to or attached to the epididymis. His view is that (a) and (b) arise from obstruction but that obstruction does not necessarily result in cyst formation. He quotes Kocher and Monod and Terrillon as having described dila tation of the ductuh efferentes and considers this to be the cause of or a later step in, the dilatation of the epididymis He considers multiple cysts to be more common and more common in the epididymis than anywhere else He also considers that (a) and (b) are retention cysts resulting from obstruction.

In the past 3 years I have seen some 12 cases of single cyst formation in the region of the mediastinum testis occurring in men under the age of 25 years. A colleague aged 43, has had one since puberty The large majority of patients were quite unaware of any abnormality and in most cases no com ment was made on it. (It is rather extraordinary how many cases of large scrotal hernia of which the patient is quite unaware are discovered at routine medical examination.) These cysts vary in size from that of a pea to a hazel nut. They give use to no symptoms or disability and therefore the opportunity for surgical intervention—certainly in the Service -is rare In those that have been aspirated the fluid has contained scanty spermatozoa. I believe that these cysts form where there has been a partial failure of the urogenital union just after the commencement of spermatogenesis.

CARE 4. Presented himself with a left inguinal bernia On examination a cystic swelling the size of a small nut was found in the region of the mediastinum of the right testis. Aged 24 he was upaware of this and therefore had no idea as to how long it had been present. At operation after the hernia had been repaired an incision was made in the right scrotum and the cyst was found lying against the epididymis, deep to the tunica vaginalis (Fig. 5) It was rather pear-shaped with the narrow or tailend toward the testis. In the cyst fluid were scanty faintly motile spermatozoa. The cyst appeared to be a distended vas efferens

I have noticed that occasionally after endidymectomy a cystic swelling forms in the region of the mediastinum testis. It makes its appearance within a few weeks of the oper ation and may grow to the size of a hazel nut. In 2 such cases in the last 18 months scanty spermatozoa were found in aspirated fluid After aspiration the cvat refilled within a few days. It has all the characteristics of a sper matocele and has occurred when there is a complete absence of union between the testis and the collecting system.

#### SUMPLARY AND CONCLUSION

Fallure of the urogenital union has received only scanty attention in medical literature and very few cases have been described. Three cases of complete failure of union occurring in a series of 42 adults operated upon with a complete descent of the tests are now re ported. It is thought that complete fallure of union occurs only in association with indecended testis. Incomplete failure of union is put forward as a suggested cause for the or currence of single mediastinal cysts in your adults.

# PRELIMINARY REPORT OF A METHOD FOR THE PRE-VENTION OF LEAKAGE OF INTESTINAL ANASTOMOSES An Experimental Study

JOHN DEVINE, MS (Melb) FRACS Melbourne Australia

THE methods herein described were evolved for colon anastomoses but are applic able to all other gastrointestinal anastomoses, including small bowel anastomoses, gastroenterostomes and dosure of the

It was noticed both in the postmortem depart duodenal stump ment and in instances in which experimental sutures had been put into redundant exteriorized colon (when it was brought out of the abdominal wall after the operation of excusion of the rectum) that each particular suture hole became infected and therefore a potential source of sepsis or leak age. Thus sutured anastomosus of the colon must always have an element of risk, and although with the bringing of pentoneum to pentoneum with silk sutures which traverse only peritoneum (where this is present) the risk is minimized its dangers in any but the most experienced hands has led in many cases, to the adoption of Paul Mikultez procedures followed by nonsuture anasaseptic anastomoss techniques, and many other methods. It tomosis with a crushing clamp has been long recognized that the most important sutures are those that bring peritoneum to peri toneum and in some methods of anastomosis no attempt is made at mucosal appoation by suture Another method of nonsuture anastomosus is the Murphy button This method gave safe anastomoses of the small bowel with pentoneum to pentoneum junction without su tures (where the bowel is covered by peritoneum) although the button is seldom used these days. Anastomoses in parts of the bowel not completely invested by peritoneum are most difficult to accomplish successfully by any method

The problem of suturing the large intestine can be considered to be comparable to suturing the inner tube of a motor tire. Here sutures cannot be employed to repair rents because each stitch put into the rubber tube would leak air therefore punctures in tires are mended by 'vulcanizing on patches over the holes.

The method herein described involves the 'vulcanizing on" of peritoneal grafts or split skin From the Physiological Department, University of Melbourne.

grafts over the suture line, whether or not the sur face is covered by peritoneum. It is a procedure supplemental to the usual methods of anastomosis. It takes very little more time and there is nothing to lose if it fails.

## METHOD EMPLOYED

In 1943 Sano reported a method of 'sticking on skin grafts using dried plasma and leucocyte cream the graft was placed in contact with the recipient area without sutures. Adhesion occurred in a few minutes. In 48 hours the graft had a blood supply and was completely fixed in 4 days. Young and Favata in 1944 further simplified this procedure using thrombin solution on the unwashed skin graft, and normal pooled plasma on the recapient area This method has been used successfully by the author in applying akin grafts cut with the dermatome, thus avoiding the necessity of sutur ing the graft in position and of applying pressure. Further work by Cannady (1943) had shown that strips of skin were useful in repairing a hernia and that no harm came from dermis in the tissues.

An experimental study was therefore under taken to see whether skin or peritoneum could be grafted over the suture line of colon anastomoses on the assumption that any method which would be successful in the colon would be at least equally successful in the small bowel and stomach. The method of fibrin fixation of a graft to bowel would be physiologically sound as after all the normal formation of intra abdominal adhesions must occur by that method Fibrin fixation of skin grafts was an established fact and had been personally found useful. However it remained to be seen whether pentoneum would receive peritoneal grafts whether intracolonic pressure would 'blow off grafts whether soiling and consequent sepsis would prevent the graft from taking whether such a convenient strong grafting ma tenal as skin or split skin could be used in the peritoneal cavity

## EXPERIMENTAL PROCEDURES

Dogs were used in the experiments because they have a strongly mobile small colon which

Fig Experiment Showing most of free omental graft still sticking t the suture line.

makes surgical procedures difficult and are susceptible to general peritonitis therefore, it followed, that they were suitable for testing the efficacy of the graft. Ten small dogs were used

Group C Exteriorized colon.

Whole thickness skin and peri- toneum	Both adhered and remarked adherent	

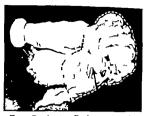

Fig. 2. Experiment 2. Showing omeutum stack experitoneal graft which was also firmly stuck in position

in the first 6 differing trial techniques were used. and in the succeeding 4 at a later date a more or less standardized technique was followed. In all cases the ascending colon was cut across between rubber bowel clamps to stop undue fecal contaminstion, and then the ends were joined together by a single continuous through-and through alk sutare which went through all bowel wall hvers at once and encircled the bowel and was ned only when it came back to the place from which it started This admittedly inadequate method of anstomosas was not assisted by the use of either a Miller Abbott tube or an artificial anus to take tension off the suture line. In some cases ieces could be observed to issue from the ineffective suture line immediately after the removal of the clamps, and in the control experiment in which this suture was used alone, death occurred wither 24 hours, and it was found that the abdominal cavity was full of feces. It will thus be seen that the greatest possible strain was thrown on the grafts in testing their efficacy in the prevention of leakage of intestinal contents.

#### RESULTS

In the first 6 experiments various procedure were used but in only 1 case (Table 1) was the grift applied with pressure. This dog fixed and was killed at the end of a week, when the gut was found stacking firmly in position without ay sign of leakage or peritonitis. (In the dog is which no graft of any sort was used, desthocaured within 24 hours with feess being widespread throughout the peritoneal cavity in the remainder in which whole thickness akin, perioneum and omental grafts were used, all ore found to be firmly stuck on to the anastomess despite the fact that pressure during application had

Fg 3 Experiment 5 Showing skin adherent to suture hoe with 'no pres

not been used but in these cases (with 'no pressure technique) leakage had occurred at one spot or another usually at the mesentenc border

In the second series of 4 cases, peritoneal grafts only were applied with pressure for about 5 min utes. No sutures of any sort were used to fix or to hold the grafts in position in these 4 cases 2 were alive and perfectly well at the end of 6 days, and when they were killed no pentonitis was found In each of these cases the graft was strongly fixed in position In one other case death occurred in 48 hours from a general hemorrhage through out the peritoneal cavity no peritonitis being present and no bowel leakage having occurred and the graft was still firmly fixed in position The fourth died after 72 hours with general peri tonitis. The graft in this dog was accidentally perforated in cutting but it was applied with the hole over the suture line just to see what would happen This graft was stuck firmly in position and could not be pulled off the bowel but feces leaked through the hole in the graft (Fig. 5)

Thus all 5 peritoneal grafts which had been applied with pressure stuck firmly in position and of these 2 dogs died 1 from hemorrhage and a from leakage through a hole in the peritoneal of graft made while it was beang taken (Fig. 5) of graft made while it was beang taken (Fig. 5) die of grafts were found adherent at least in part In grafts were found adherent at least in part In the experiment in which no graft had been applied to the suture line a peritoneal graft applied to the colon elsewhere was firmly adherent.

The application of these findings to the human was first done on exteriorized redundant bowel left outside the abdominal cavity after the operation for exclaim of the rectum A graft of whole thickness skin and a graft of pentoneum were both taken at the time of operation and refrigerated taken at the time of operation to the exteriorized for 6 hours before application to the exteriorized

Fig 4. Experiment 7 Showing peritonesi graft stuck firmly in position.

colon on its peritoneal aspect, plasma being applied to the bowel and a few drops of thrombin solution to the graft ressure was applied for 4 solution to the graft adhered readily. They were firmly fixed in 24 hours and by the third day firmly fixed in 24 hours and by the third day the appeared to have a blood supply and by the fourth day the edges could not be lifted. The fourth day the edges could not be lifted. The fixation was easier than with dog plasma band as much more sticky than dog plasma and of course human bowel and skin and pentioneum are much larger and easier to handle pentioneum are finly dog peritoneum and small dog to colon which had presented many technical difficulties in the spreading of the graft.

Fig. 5. Experiment 8. Showing edematous peritorical graft struck firmly in position with arrow pointing to hole in the graft through which solling of the peritorical cavity had occurred.

Fig. 6. Experiment o Showing mass of omentum adhering to peritoseal graft such was family fixed in position.

Observation of the grafts in the dogs and man shows that they adhere with a reasonable tenacity immediately that by 48 hours they are quite firmly adherent and that at the end of a week they could not be pulled off. After 48 hours the grafts appeared to be edematous and to stay so for some days.

It is reasonable to suggest therefore, that the employment of these grafts in intestinal anastomoses in man will be of great value and may obviate the use of staged operations now commonly performed in order to avoid the risk of leakage from the nuture line.

#### PROTOCOL OF EXPERIMENTS

In all cases a right upper paramedian abdominal incusion was made and the ascending color cut across about 4 inches from the occum. The ends were then joined together with a continuous silk

Fig. 8 Clamps used by author

The possible human applications of these find also firmly freed in position. ings ou dogs and the human bowel are that with the usual methods of anastomosis as used in either gastroenterostomy operations on the esophagus, gastrectomy closure of the duodenal stump and small or large bowel anastomoses, the suture line can be very rapidly reinforced by a strip of antenor peritoneum sufficient to go round the bowel and with a little to spare and about three-quar ters to an inch in width This would be moistened, with a few drops of a solution of 5000 units of thrombin in 5 cubic centimeters of saline and applied to the suture line which has been swabbed with pooled human plasma, most conveniently obtained from a blood bank. Both these solu tions keep a long while in the refingerator and indefinitely in the desiccated form. This procedure could be done whether or not there is pertoneum on the suture line Pressure would then be applied for 5 minutes by medium of some such type of clamp as used by the author (Fig 8) and then the intestines would be carefully returned to the abdominal cavity if handled roughly in its early stages, the graft may be rubbed off before becoming firm As a further precaution and where anatomically possible omentum could be moistened with thrombin and applied to graft and bowel which has been painted with plasma. This will then adhere and form artificial adhesions as was shown in experiments 10 and 2. Thus a rapid and easy means of omental reinforcement of suture lines is available Further for some time it has been the practice of the author before suturing to moisten with thrombin solution one side of intestines being anastomosed and the other side with plasma solution Thus the normal scal ing and repair of bowel are speeded up during the few important hours when the bowel is quiescent following laparotomy

# BUMMARY AND CONCLUSIONS

The theoretical basis of a quick, easy method of increasing the safety and scope of a gastrointesti nal tract anastomosis is described. Experimental results in dogs and application in a human being are brought forward in support of this method

# UTILIZATION OF HENLES LIGAMENT ILIOPUBIC TRACT APONEUROSIS TRANSVERSUS ABDOMINIS AND COOPERS LIGAMENT IN INGUINAL HERNIORRHAPHY

#### A Report of 162 Consecutive Cases

JOHN H. CLARK, M.D. Major M.C., AUS., Vernal Utah, and EDWARD I. HASHIMOTO MD Salt Lake City Utah

November of 1943 because of the urgent need for replacements in the Army it was decaded to induct those men who previously had been deferred because of inguinal hernias. The Station Hospital, Fort Douglas, Utah was called upon to rehabilitate many of these men as it is adjacent to a reception center and it seemed advisable to keep them near home until they could undertake basic training

To plan an operative technique that would make recurrence under the strain of training and combat less likely we decided to review available hospital operative records on recurrent hemias to determine the point at which they had broken through the abdomnal wall. It was found that 75 per cent had recurred as direct hernias superior to the pube tubercle, and posterior to the external abdominal inguinal ring [Fig. 3]. The remainder had occurred as indurect hemias probably from incomplete obliteration of the sac.

Many of the standard methods of repair of inguinal hermas have employed the principle of suturing the conjouned tendon to the inguinal ligament to reinforce the posterior wall of the inguinal canal. Surprisingly little attention has been paid to the utilization of other tough tissues that exist in this area namely the strengthening fibers in the transversalis factor.

McVay and Anson have recently called attention to the anatomy of the Ingunal region and have reanalyzed the structures in that area. They have found considerable variation between their careful dissections and the descriptions ordinarily occurring in standard textbooks, particularly with reference to the transversalls fascua and the conjoined tendon.

#### TRANSVERSALIS FASCIA

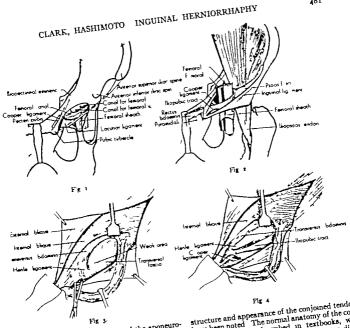

Most texts inadequately describe the transversalis fascia as a structure lining the inner sur

From the Department of Anatomy University of Utah School of Medicine, Salt Lak City and the Station Hospital Fort Douglas, Utah

face of the abdominal musculature (Fig. 3) In our dissections of the inguinal area we found that the transversalis fascla consists of three promines fibrous structures with intervening connective structures with intervening connective fibrous structures with intervening connective fitsure. These three fibrous remiforements of the transversalis fascia are the fliopuble tract, finds ligament, and the aponeurosis of the transversal addominists. For a more detailed description of the anatomy, the work of McV ay and Amon should be consolited.

Riopubic tract The transversals facts is directly continued into the thigh as a part of the femoral sheath. When this fascia is dimerted from the inguinal ligament, care being taken at to open the fascus there is a band of fibers pand leling the inguinal beament and demarcating the abdominal component of the fascia from that of the thigh It can be palpated as a tough, fibrost structure posterior to and separate from the inguinal ligament and cannot be seen unless a s separated from that ligament (Fig 4) The tast is best seen anatomically by severing and retracting the inguinal ligament (Fig. s) It a d considerable strength passes inferior to the internal abdominal inguinal ring and may be traced from the illopsons (paces) fascus in the area of the anterior inferior lilac spine to the public tubercle (Figs. 1 2) Medially blending with Henle's ligament, the aponeurosis of the transversus abdomins and other less promises portions of the transversalis fascia, the fibers of this tract insert into the pubic tubercle and Cooper a ligament (Figs. 5, 6) This band of fibers of the transversalis fascia, the illopate tract, has always been present and was comidentified It is a separate structure from the agumal ligament.

Heales i spaces! Without entering his are historical controversy concerning Heale's Epment (McVs) et al.) we found in all of our desections a definite fibrous structure, which seems to be derived in part from the lowermost ports of the lateral border of the rectus sheath, and is

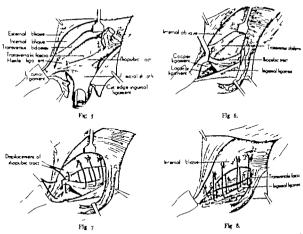

part from the lowermost extent of the aponeurosus of the transversus abdominis (Fig. 3) Fan ning out interolaterally it intermingled intimately with the fibers of the lhopuble tract (Fig This is the structure originally described Henle

Aponeurosis of the transversus abdominis The lowermost fibers of insertion of the transversus abdominis muscle are aponeurotic and appear as a flat band paralleling the lateral border of the rectus sheath (Figs. 3 5) Superiorly some of the fibers pass anterior to the rectus abdominis muscle and form part of the anterior wall of the rectus sheath while interiori) some pass down to blend with Henle's ligament The major portion of these fibers, however insert into the pecten of the publs (Fig 6)

## CONJUDINED TENDON

In our experience both in the dissecting room and the operating room wide variations in the

structure and appearance of the conjoined tendon have been noted The normal anatomy of the con joined tendon as described in textbooks, was frequently observed although often it was diffi cult to differentiate the conjoined tendon from the lateral border of the rectus sheath cally the conjoined tendon is described as a com mon tendon of those fibers of the internal oblique and transversus abdominis muscles which form an arch over the spermatic cord (round ligament in the female) and insert into the pubic tubercle and the pecten of the publs. More careful analysis of our dissections show that this so-called tendon is composed of two sheets of tissue representing those portions of the aponeurosis of insertion of the internal oblique and transversus abdominis muscles lying anterior and in small part lateral to the rectus abdominis muscle insertion These two aponeuroses are not a fused tendon as usually described but two distinctly separable aponeu-TOSCS.

Some of our past difficulties in explaining the conjoined tendon to ourselves and to the discern. ing student lay in the fact that the aponeurotic insertion of the internal oblique falled to reach the pubic tubercle or the pecten of the pubis, but inserted into the anterior rectus sheath interdigitating with fibers of its fellow several centimeters above the usual point of insertion Moreover in some dissections it was found that the aponeurotic insertion of the transversus abdomin's was into the lateral wall of the rectus sheath as described by Robins. These abnormal insertions of the internal oblique and transversus abdominus muscles leave a weakened area superior to the pubic tubercle and posterior to the external abdominal inguinal ring (Fig. 3) the site of most recurrent hernias (Babcock, and Robins) The only structure present in many of these dissections reinforcing this area was a weakened transversalis fascin

#### COOPER S LIGALIENT

In addition to the structures described another important ligament exists, which extends from the public tubercle along the pecten of the publis and continues posteriori) along the libocritical line at an angle of approximately 30 degrees to the inguinal ligament (Figs. 1). It disappears are the Iliopectineal eminence by blending with the periosteum of the bone, and is minutely scheen to the bone in its entire extent. Because of a strength and position it would seem only ight that it must have considerable importance. In are attached from below upward the period fascin the lacunar ligament, the apocenor thuckening of the transversus abdominis, Heak's ligament and the remaining less distinct portion of the transversals fascia (Figs. 5, 6)

In the Iraniversation in the Court of the Iraniversation and Swemson have reviewed the literature and pointed out that the saturage of the Iraniversation fascial and attached streams of Cooper's ligament was not new Such men as Cooper's ligament was not new North of Cooper (1921). Stetten (1923), Andrew (1924). Keynes (1927) Sketten (1923), Andrew (1924). Keynes (1927) Pakkond (1927) Dekkond (1924). McClure and Fallis (1923) Amendoli (1924). Newboft (1924) and Harkins et al. (1924) have used this structure, and been satisfied with a importance in the repair of hernias of the repea

#### THE REPAIR

The technique presented herein has been deloped and tested on 162 inguinal hernlas of all pes. To date there have been no recurrences. t the time this work was started we were not

Unless contraindicated all of our hermorrha hies are done under spinal anesthesia. Regard ess of the type of hernia to be repaired a skin ncision is made as originally described by Bassin clamping the superficial vessels before they are severed. The aponeurosis of the external oblique is cleaned of all fat and arcolar tissue by sharp dissection, and a small incision is made in the direction of the fibers of the external oblique, near the upper margin of the wound The incinion is carefully enlarged with scassors until the illoinguinal nerve is exposed and dissected free, and the ilhohypognstric nerve is identified (Damage to these nerves may result in an annoying skin anesthesia and a loss of tone of the internal oblique and transversus abdominis muscles favoring a recurrence of the hernia.)

The incision is then extended down through the external ring and with a moist gauze sponge, the aponeurosis is cleaned down to its insertion. The pubic tubercle is clearly identified and all areolar tissue is cleaned from it with a sponge The sheath of the cremaster muscle is not opened but is detached from the inguinal ligament with a most sponge. After the cord has been mobilized, it is held with an Allis forcep if small or with a rubber tape if large enough to be constricted by

The indirect sac is identified and picked up at the anteromedial surface of the cord It is incised an Allis. and freed from the surrounding structures by carried out through the incision in the indirect sharp and blunt dissection ac for a direct sac, and if one is found it is transposed lateral to the epigastric vessels, converting both sacs into one (Hoguet) It is necessary to identify the micrior epigastric vessels and to separate some prepentoneal fat from the indirect sac and to visualize and dissect the bladder away from a large direct sac before dissection of the sac is complete. Failure to do so may result in a recurrence of the hernia The sac is closed with a pursestring suture and usually transfixed under the transversalis fascia and internal oblique muscle although this step may not be necessary if the sac dissection is complete.

In order to avoid subsequent confusion in the identification of the structures used in the repeir the internal abdominal oblique muscle is identi fied and held with an Allis forcep This step

avoids later inadvertent suture of the muscle and its aponeurous to the deeper structures

Next Cooper a ligament is palpated as a tough, ndge-like band extending from the pubic tubercle along the sliopectineal line (Figs. 1 2) The transversalis fascia is then separated from the inguinal ligament and the underlying lacunar ligament in the area adjacent to the pubic tu bercle by means of a small straight forceps (Fig. 3) and the anterior 2 centimeters of Cooper's ligament exposed (Fig 4) Unless this separation is carried out close to the pubic tubercle the transversalis fascia will be entered and preperi toneal fat encountered, so as to interfere with

subsequent suture (Trowbridge) Further digital separation of the transversalis fascia from the inguinal ligament exposes a tough fibrous structure the iliopubic tract and the underlying femoral sheath (Figs. 4, 5 0) By clearly exposing the iliopuble tract and mobilizing the femoral sheath a procedure not previously described in the literature, we avoid accidental injury to the femoral vein or artery (Figs. 2 5)

Gallie transplants of fascin lata, obtained with a Masson fascia stripper are preferred to any other suture material for recurrent direct and acrotal indirect hernias. When fascia lata is used the first strip (1 centimeter wide and 15 to 20 centimeters long) is anchored into the periosteum and tough structures overlying the pubic tubercle (Fig 7) From this point a continuous running fascial suture is used. Henle's ligament is then brought down to Cooper's ligament. Next the Gallie needle is passed successively through Henle's ligament Cooper's ligament and the medial portion of the illopubic tract closing the weakened area in the transversalis fascia, the site of most recurrent hermas. At the same time, the lliopubic tract is displaced shortened and drawn diagonally across the area occupied by the femoral canal, to close the canal (Figs. 1 2 3 7) This procedure is technically less difficult than sutur ing the aponeurous of the transversus abdominis to Cooper a ligament in the relatively maccessible region of the femoral vein (McVa) 1942) and per mits clear visualization of all structures used in the repair The suture is continued (Fig 7) attaching the lowermost margin of the aponeu rosts of the transversus abdominis to the iliopubic tract, folding under and obliterating the rela tively weaker areas of the transversalis fascia When the internal abdominal inguinal ring is reached it may be closed tightly without en dangering circulation of the cord. The end of the fasdal strip is then anchored with interrupted No 40 cotton sutures.

The same technique is employed in less difficult repairs with interrupted No 20 cotton autures.

This repair of the transversalis fascia and its reinforcing structures produces a strong berrier to recurrence of hernias. While there may be no necessity for further repair of overlying structures (McVav et al ) on the other hand. In most cases it is a very simple procedure to suture the lowermost marron of the internal abdominal oblime muscle and its aponeurosis to the inguinal ligament, by means of a feared strip or interrupted No 20 cotton sutures, after the method of Bassini (Fig. 8) We do not heritate to use muscle for this second layer when the anoneurosis is deficient. Dissections of recurrent bernias have convinced us that the colmysium of the muscle will become firmly adherent to the ingrunal ligament. Occasionally it is found that the anomalous aponeurotic insertion of the internal abdominal oblique muscle cannot be easily approximated to the inquinal brament. In that event a relaxing incision in the rectus sheath is made (Rienhoff) and the fascia overlying the nymmydalis muscle, the lateral border of the rectus sheath, and available fibers of the internal abdominal oblique and its anoneurosis are then sutured to the shelving margin of the inguinal ligament. Either method of suture produces an additional atmng barner and although we feel that the second layer is the least important of the two nevertheless, the Bassini operation has cured many thousands of cases. Therefore, we have used this additional precaution.

The aponeurosis of the external oblique is repaired loosely over the spermatic cord, and the external inguinal ring is not made unduly small. We do not believe that the aponeurous of the ex ternal oblique can be of much significance as a barrier to recurrent hernias, once the posterior wall of the inguinal canal has broken down

#### STIMMARY

With certain anatomical facts as a basis for a rational reconstruction of an maumal hernia, the described operation was devised. It completely closes the weak area superior to the pubic tubercle and posterior to the external abdominal inguinal ring. The salient features are

I By separating the loosely attached transversalls fascia from the inguinal and lacunar ligaments at their most inferior portion (close to the pubic tubercle) and stripping the fascia from the ligaments, a strong band of fibers is exposed the illopubic tract (Figs. 3 4, 6)

2 As an initial step Henle's Brament rel adjacent portions of the aponeurosis of the tree versus abdominis are sutured to Cooper a firement along its anterior one-third, an available arrive of approximately 2 centimeters. This results is no undue tension, whereas, suringer these state tures to the entire length of the ligament, namely back to the area of the femoral vein, does reach a definite tension and requires a relaxing inches in the rectus sheath

3. The weak area of the transversely freely is further strengthened by attachmy the transposus abdominis anoneurous to the illombic text as far as the internal abdominal incumal rise (Fig. 7) This produces a strong pleat of transversalis fascia and raises and displaces the liepublic tract closing the former defect (Fig. 7) At the same time this step produces a tight intered abdommal rung and closes the femoral caral.

A second barrier may be constructed by suturing the aponeurotic lower fibers of the inter nal oblique muscle to the ingumal ligament the the method of Bassini. If this aponeurous short be deficient, a suture in the rectus sheath or in the aponeurosis of the transversus abdomins is take, medial to that described in paragraph 3, and the layer sutured to the ingumal houment. Rarely s a relaxing incision in the rectus sheath required

5 The aponeurosis of the external oblique a repaired loosely over the spermatic cord, and the external abdominal inguinal ring is not made

unduly small.

6 Strips of fascia lata have been found to be the most suitable suture material for the repair of recurrent, direct, and large scrotal indicat hernias

# EARLY POSTOPERATIVE RISING

# A Statistical Study of Hospital Complications

# JAMES B BLODGETT MD and EDWARD J BEATTIE, MD Boston Massachusetts

THERE has recently been a revival of in terest in early postoperative rising and walking In June 1942 a critical study of early postoperative ambulation was undertaken at the Peter Bent Brigham Hospital. The preliminary results of these studies are the

basis for this communication. Ries in 1899 was the first to report on the subject of early postoperative rising. He had noted that his gynecological patients who rose from bed shortly after operation were considerably stronger that as a group they had a low incidence of post operative complications and that there were no demonstrable ill effects of early rising The early nsing technique was not then widely accepted in this country but in continental Europe it has been extensively used from 1999 until the present time. The recent revival of American interest in this subject began in 1941 when Leithauser (4) reported a series of 436 cases. Newburger (5) has published an excellent review of the American and foreign literature on the subject and also experi mental data of his own (6) from rats. Newburger s experiments showed increased strength in wounds of animals in the early postoperative period if they had been given postoperative exercise. Chinical papers have been published by Leithauser (3) Nelson Nixon Powers, D'Ingianni, and Schafer and Dragstedt. All these authors are impressed by the rapid return to full strength of their early rising postoperative patients and by the apparent early reduction of wound discomfort. Almost all of them note a low incidence of pulmonary com plications and of deep phlebitis of the legs. The latter three reports are the only ones in which any comparisons are drawn between a series of early rising patients and a control series. The definition of what constitutes early rising has not been very strict as some authors include in this group patients who have risen as late as the 4th or 5th

In order to arrive at an accurate appraisal of the day after operation. results of early rising cases must be compared under as similar circumstances as possible. Since the incidence of pulmonary and vascular compil cations appears to vary in different parts of the

From the Sergical Clinic of the Peter Bent Brigham Hospital, Boston, Massachusetts.

country the results of an early rising series in one region cannot properly be compared with those of a control series from a different region. The two series are most accurately comparable if they are observed in the same clinic.

In order to emphasize any appearent changes in postoperative complications this study is limited to the type of operative case in which the compil cations most commonly occur that is, patients having major abdominal surgery who rose from bed either on the first or second postoperative day are considered in the group of early users. These are compared with patients who remained in bed at least 1 week after operation.

This study compares 238 consecutive cases in which early rising was practiced with 443 in which it was not. The factors considered as possibly bearing on the incidence of complications were (1) age, (2) sex (3) type of anesthesia, (4) type of incision (upper vertical lower vertical and

The operations performed through upper abdom hal incisions were on the biliary tract stomach The operations through lower incisions were on the small and large bowel female internal genitalia, and occasionally the appendix. The procedures through McBurney incl sions were all appendicectomies. The suture tech nique was that of interrupted fine silk to all lay ers except the peritoneum where continuous chromic catgut was used

The complications studied were (1) pulmonary (atelectasis, pneumonia) (2) vascular (phlebitis, pulmonary infarct) (3) wound (disruption, in-

Our technique of getting the patients up from bed is modeled after Leithauser (4) The patient lection) Is turned upon the side on which he has his incison. The hips and knees are flexed. Thus the kness and lower legs are brought to the edge of the bed. The patient is then rulsed sideways to a sit ting position on the side of the bed. The advan tage of sitting up in this manner is that as the patient assists in raising himself he uses the flank muscles on the side opposite from his wound. As the patient sits on the side of the bed his shoes are

put on and then he stands up on a foot stool While standing on the foot stool, he is encouraged to breathe deeply and to cough several times after deep mapiration. This procedure is less poinful than when the patient coughs in bed and is often effective in raising mucous plugs from the bronch. He is now encouraged to walk 8 or 10 feet before sitting in a chair. On the first rising the patient remains in the chair about 10 minutes, and then returns to bed in the same manner as he rose. Our patients were gotten up twice each day. Usually by the third or fourth day they needed little or no assistance and could rise at will. All the patients were encouraged to move freely about in bed and to breathe deeply several times each hour

#### RESULTS

The most striking effect observed in early rising patients is the rapidity with which they regain their strength. In point of fact, they do not seem to loss strength. They are more active in bed, and their wounds are less dashling. On the fourth postoperative day most of the early rising patients had very little wound discomfort and got up unassisted. At this time they became ambulatory patients and required very little nursing care. As a result of this early strength and freedom from pain, most of the patients requested that they go.

home earlier than the non-early rising patient. We did not feel purtified in sending our patient bome before the several to ninth postoperalized by because not until then could we conside that the time for appearance of wound meterion or for ruption had passed. In spite of this, 40 per or of the early rising patients were discharged byte the 13th postoperative day while only 96 per or of the control group were discharged by this one. At the time of discharged, those of the card risks group were strong and able to do a great dealf were themselves in contrast to the group who had a mailted in bed for to to 13 days and were seaff discharged to 2 a days after return out of held

#### INCIDENCE OF COMPLICATIONS

Table I lists the overall incidence of complications. The complications in the patients who rue on the second day are separated from those was rose on the first day so that a more accurate pe ture will be given. As this study was begun, se were concerned lest there be a marked increase is the incidence of wound duruption among the early rising group. It is seen that instead of increase incidence of wound disruption, the early rises group had a slightly lower incidence of wound do ruption. Likewise the incidence of pulmorary complications was reduced. The incidence of viscular complications, however was somewhat itcreased. None of these increments are, as yet, it miscantly greater than the standard error of ther difference but they point the trend. The trend

toward earlier discharge from the hospital is seen in the greater percentage of the test group who were discharged early. This reduction in hospital days required and the fact that the patients who have risen early need less care represents a definite reduction in work for the ward personnel.

Pulmonary complications The diagnosis of arthertasis was made in our patients on a clinical bans if there was a postoperative use in temper attire associated with rikes and elevated respir atory rate in the absence of other demonstrable cause for fever. The diagnosis was also made if there was x ray evidence of atelectasis. The in cidence in the first day using group was 4.3 per cent of 3 per cent in the late rising group.

Table II is a comparative chart of the pulmonary complications analyzed for their various ethological factors. The familiar greater incidence of atelectasis in upper abdominal vertical wounds is seen in both groups when the cases are divided with respect to the location of the abdominal wound. It is significant that no case of atelectasis occurred in the cases with low abdominal wounds who rise on the first day.

Analysis for the sex factor shows that although the incidence of atelectasis in men who remained in bed was high it was unusually low in those who rose on the first day after operation. The incidence of atelectasis among the females of the two groups is essentially the same.

The analysis for the type of anesthesia shows no significant variation in the incidence of atelectasis

in either group whether ether or spinal anesthesia was used.

The influence of the age factor repents the familiar pattern of increasing incidence of stelectasis with advancing age in both groups.

Pneumonia was such an infrequent complication that it does not permit comparative analysis.

I ascular complications. The term phiebitis is used in this discussion to include both aient thrombods (phiebothrombods) and deep phiebitis of the legs. The disgnosis of deep leg vein phiebitis was made on the basis of tenderness in the calf muscles, associated usually with one or more other signs i.e. a positive dornsifiction (Homans?) sign edema of the lower leg or a rise in pulse rate temperature, or white count. Also if a patient had pulmonary infarct or embodism in the absence of heart disease, a presumptive diagnosis of phiebitis was made. The overall incidence of deep vein phiebitis among the early raing patients is seen to be greater than among those who did not rise carly (3 per cent vs. 18 per cent). See Table III

Analysis of the incidence of phiebits with respect to the placement of wounds shows that there was no phiebitis recorded in any of the McBurney incisions whether they rose early or not. The females had a higher incidence of phiebitis than the males in the first day rising group. The high est incidence of phiebitis in the non using group was in the patients of oo years or more, but in the early rising patients, the highest incidence was in the group between so and for years.

This observed increase in the incidence of post operative deep phlebitis of the legs is not great enough to be of irrefutable statistical aignificance. But it is significant that our data do not agree with many of the previously published clinical impressions that early rising produces a reduction in the incidence of phlebitis. Early rising is apparently not the answer to the problem of postoperative venous thrombous.

WOUND COMPLICATIONS Considerable interest was attached to the posibility of increase in wound disruption which might occur from the increased stress put spot its wound in rising from the bed and walking abort Wound disruption is here defined as any wound a which the fascla is shown to have separated whether or not the perstoneum remained hast Our data (Table IV) show an actual relation is

wound disruption in the test group. Among early rising patients there was I I per cent of wound disruption whereas in the non-name patients, there was 2 8 per cent incidence of wound disruption. The known higher incidence of wound disruption in upper abdominal incisions was demon strated in both series The two McBurney incisions that had wound disruption were those in which drains had been used.

The incidence of wound infection among the early rising patients was 2 7 per cent as compared with 5.7 per cent in the patients who rose late. This group includes all types of infection includ ing stitch abscesses.

It is interesting to note that all of the wound in fections in both series appeared in patients with potentially contaminated wounds. Of the 5 pa tients who had infected wounds in the early rising group there were a patients who had cholecystectomies and a patient who had an appendi cectomy for acute appendicitis. Of the 25 patients who had infected wounds in the non-early rising group 11 had appendicectomies, 10 cholecystec tomies, I a perforated ulcer and I a resection of the large bowel.

#### EVALUATION

We have now observed the technique of early postoperative rising for a years. Data on a control series of intra-abdominal operations are presented herewith. The most remarkable observation is that postoperative activity tends to maintain the patient's strength and endurance whereas prolonged rest leads to increasing weakness and It also appears that muscle muscle atrophy activity in the region of the wound has the tend ency to reduce the period of wound tenderness but it does not increase the incidence of wound distuption.

Early rising appears to reduce the incidence of postoperative atelectasis. This may be due to increased respiration and more effective coughing, especially when the patient is standing when his diaphragm can descend to lower levels (3) Since atelectasis most frequently appears during the first 48 hours after operation, the patient should be gotten up as soon as possible within that period if rising is to have a significant effect on prevent ing atelectasis.

In our experience the incidence of phlebitis or phiebothrombosis of the deep veins in the legs is not reduced by early postoperative walking. Our data agree with the published impression of D'Ingianni who observed early rising patients in New Orleans. There may be certain precautions which can be observed to minimize call muscle trauma when patients rise from bed. These are however equally important at any time in the postoperative period.

There was no greater incidence of wound disruption and infection in our patients who rose carly

#### SUMMARY

A controlled, preliminary study of early post operative rising and walking is made on patients having major intra abdominal surgery. A total of 681 cases were analyzed for postoperative complications and their causative factors. Early rising is defined as rising and walking on the first or second postoperative day

The patients who rose early were connderably stronger and had less pain in their wounds. They were able to care for themselves on about the fourth postoperative day and were ready for discharge considerably earlier than the control group

The incidence of wound disruption and wound infection was reduced in the early rising group

The incidence of pulmonary complications was somewhat lower in the early rising group

The incidence of deep leg vein thrombophichitis was observed to be somewhat greater in the early rising group

It might be postulated that some of the lat rising group develop signs of phicities of the leg wins at home several days after dacharge, so, it has not been apparent in the follow-up visits which are made days to vessio after ducharge.

#### RESTORATION OF CONTINUITY VERSUS CURE IN CARCINOMA OF THE RECTUM

HERE is a widespread revival of operations designed to preserve the rectal sphincter in patients with carcinoma of the rectum and rectosigmoid. This aim to preserve the sphincter is a natural outcome of advanced surgical akili and tech nique on the one hand, and on the other of evidence that primary spread of disease from this region is cephalward. At this time we must carefully weigh the evidence of experience and adopt a rational attitude regarding the problem.

Given a patient with carcinoma of the rectum we must take into consideration the single fact that cure if possible is our obligation. Unfortunately many of these victims arrive in an uncurable condition—a fact due mainly to our inadequate educational methods, although at the moment there seems

to be no effective manner in which all cues can be diagnosed in an early state.

In a recent series of 100 consecutive retients with carcinoms of the rection the average duration of disease before entry into the Massachusetts General Homital was . months. Twenty-eight had such extense disease that a resection was impossible Seventy two had an abdominopenneal resection in one or two stages. There were two deaths in this group -a postonerative nor tality of 2.8 per cent. One patient died from hypertensive heart disease, and the other of a pulmonary infarct. About to per cent of the resections were done in the presence of hepatic metastases. Including the operative deaths, approximately 45 per cent of the operable cases or 30 per cent of the entre group will live 5 or more years. It appears at this time that only earlier diagnoss vil materially improve these results.

The best safest, and most adaptate operation so far devised is the combard abdominoperineal resection of Miles Technique may be varied in many sais and the operation may be done in one of the stages. This method allows the surgest is emove the local spread of the disease noticing the regional lymph nodes and extension neighboring visceria as well as to permeasurables. In skilled hands, the mortality rate is low and the morbidity is growing less with better preparation and after-care. This procedure however does leave the patient with a permanent colostomy.

Colostomy is not burdensome to thousand of grateful individuals who have been card of cancer With reasonable care they are free to carry on their business, athletic and social functions without offense or incon the venience. Sentimental abhorrence of the colostomy by patient and physician has wasted many useful lives. Although none looks forward to a colostomy life with avid joy few will refuse it if the entire situation is existed to them. Taught the simple printial concerning care of the colostomy nearly all of these patients are comfortable and happy

In performing resections with low anastomosis, one must consider the following rules governing a proper operation for malignant disease. First, have we given the individual patient his greatest chance for cure? Second have we increased his immediate hazard? Third will the morbidity from poor sphincter control or fistula formation justify the procedure? The second and third of these have

been pretty adequately answered in a satisfactory manner. The first concept is not yet determined and it will take considerable time to do so. In reporting results on these procedures surgeons must make it clear that local recurrences have not taken place in those patients whom they would have expected to cure by performing a complete expected to cure by performing a complete of timpation of the rectum and the muscles of

the perineal floor

The issue is confused by the fact that all of
the issue is confused by the fact that all of
sagree that restoration of continuity is
justifiable if the patient has metastatic dis
ease in the liver at the time of operation
These cases should not be considered in the
same light as those whose spread of disease
was limited to the resectable area at the time
surgery was undertaken

#### THE SURGEON'S LIBRARY

#### REVIEWS OF NEW BOOKS

Title book entitled Penicillis in the Traineast of Infections by Keefer and Anderson presents in its 42 pages a clear summary of what is known of penicillin and its effect, but it does not disclose any new facts about its action or administration.

tration.

Penicillin seems to act like the sulfonamides by interfering with some metabolic processes of susceptible bacteria and therefore is active only when the bacteria are in a phase of growth and multiplication. In the concentrations that are achieved in living beings its effect is chiefly bacteriostatic and not bacteriocidal. Thus it does not actually eliminate the infecting organisms but inhibits their growth and multiplication. But unlike the sulfonamides, penicillin is not inhibited by pus, peptones, or the breakdown products of tissue autolysis. The sensitivity to penkillin varies with the various species of organisms. It is not understood yet why gram negative bacilli and virus infections are not susceptible to the action of the drug por why susceptible bac term may become resistant when exposed to the drug for longer periods. However it has been shown that certain bacteria of the coli group produce a substance penicillinase, which inactivates penicillin. The sensitivity of any bacterial strain to penicillin can be determined and may be very useful in the treatments of certain infections. Of considerable importance is the fact that there is no correlation between resistance to penicillin and resistance to the sulfonamides.

Several biological assay methods for determining the concentration of penicillin in the blood and the body fluids are available. It has been found that 60 per cent of the amount of penicillin injected in the blood stream or the muscles were excreted in the urine within a hour and that little or no drug remained in the blood after 3 hours. For this reason, it became evident that the use of large doses of the drug was wasteful since a better bacteriostatic level could be maintained in the blood by the administra tion of small doses given every a to 3 hours. It has also been shown that when mixtures of penicillin in becswax and peanut oil were injected intramuscu larly, the drug was absorbed slowly and the thera peutic effect could thus be prolonged to 6 or 7 hours.

The authors recommend for the treatment of systemic infections the intermittent intramuscular administration of penicillin. Intermittent intravenous

PROVIDENT IN THE TEXAMENT OF PUTERSONS BY Chester S. Krifer B.S. M.S. M.D. Sc. D. (Box.), and Dennid G. Anderon, A.B. M.D. Mey. York, Landon, Towards Edded by Henry A. Christian, A.M. M.D. Li. D., Sc. D. (Ron.). FACT Son. F.E.C.P. (Can.) Oxford University Press, p.43.

injections or continuous intravenous or intrascular infusions offer no advantages and are conferably less convenient.

The passage of penicillin from the blood into the cerebrospinal fluid or the various parts of the ere h minimal and noneffective. Its passage into the pleural, abdominal and synovial carmes is seen what more satisfactory It is therefore recommended to inject penicillin directly into the subunched space the cerebral ventricles, the articulation the pleural cavity the cranial sinuses, the clumber of the eye, etc. Topical application of pencilla a superficial burns skin infections, and inicite wounds by means of wet dressings or robber other has given excellent results. The dorage and the next adequate way of administration are documed for the various methods of administration of penicain, the clinical aspect of penicillin therapy is presented with more details in cases of staphylococcic better emia of the face, acute hematogenous estronychia, chronic osteomyelitis, staphylococcie pocanosi, multiple subcutaneous abscesses, hemolytic stapes coccal pneumonia and empyema, gonomica, poingococcemia, pneumococcic pneumona, poemcoccic meningins, subscute bacterial endocadas, gas gangrene and syphilm. The toric reaction at rare, the more common being urticara and level.

Penicillin is without doubt the most efform agent for the treatment of infections disease. He ever it should not replace or disminish sixtu septi ascepsis, the early surgical treatment of women, as general medical prophylaris against infectors diseases. Gorger Print.

AMONG the noteworthy publications of its licit and Department of the United Stars torm Patkadery of Treylead Diseases by Ask and Sar will find a place in the first rank. It fish a seed set much by textbooks on tropleal medicine, which are found to the processing of the place emphasis on etiology chieral shows which is a collection of pair photographs, possible micrographs reconsequencement, and drawent seed without naterial in highly exceptable form, it witness that the authors had a well-the disasting hand, because nearly every illustration is one of the best possible. The technical quality of the propositions is united by the proposition of the prop

PATROLOGY OF THOMCAL DECISES: A ATLA BY J S his Clark
M.C. U.S.A., and Sopkie Split, M.D. C.S. A.U.S. Planking and
Legico W. S. Sezzders Co. 1943

Nearly every disease to be found in the tropics, from ainhum to yellow fever is dealt with. Brief explanatory notes which include enough information to orient the reader and sketches of the epidemiological facts are provided. The sallent features of each duesse are presented in excellent photographs

This is an authoritative book. Although atlases are often thought of as supplementary works this or x-ray pictures. particular one is outstanding because it is a highly intelligent contribution designed specifically to illummate where illumination is most needed. It is recom mended to students of tropical medicine and to pathologists who will be confronted with the se quelae of tropical diseases.

A LONG standing gap has been filled by Thomas and Haddan a Ampatation Prosidests' by bring ing together two authorities who have combined their knowledge to present a practical guide for surgeons and practitioners on the proper use of orosthetic appliances. This dual authorship—a urgeon and a manufacturer of artificial limbsprovides a common ground for discussion of the

The mutilating injuries of war have awakened an problems of the amputee. increased interest in amputations surgical technique and prosthetic appliances. It has been estimated that the number of amputations resulting from the First World War totaled 500,000 for all nations engaged Amputations among the armed forces of the United States were relatively small, however numbering only about 4,000. During the Civil War there were well in excess of 30 000 amputations in the Union Army alone. Figures for the Second World War released as of July 1 1945 reveal that over 15,000 amputation cases have been treated in the various amputation centers established by the Army and Navy of the United States and no doubt there will be many more before the toil of the war is The total number of amputations resulting from World War II will probably exceed a million The number of amputations performed each year

among the civilian population of this country far exceeds amoustions berformed in the armed forces even in wartime. The American Federation of the Physically Handicapped has estimated that there are approximately 75,000 new amputation cases in this country every year and that of this number 40,000 are major amputations requiring prostheses. National Safety Council has reported that, prior to World War II 32 500 amputations resulted annually from accidental causes alone. Reliable estimates reveal that there are now approximately 925,000 amputees living in the United States. The artificial limb manufacturers of this country report that prior to the present war they were supplying prostheses to more than 70,000 persons annually

ABFORMUM PROTESSES AMPOSED AND PROTESSES COMMUNEAU SERVE, WITE PRINCIPLES OF ALBERTAIN AND PROTESSES OF ALBERTAIN AND PRODUCED AND PROTESSES OF ALBERTAIN AND PRODUCED AND PRO

In the past, too little attention has been paid by surgeous to the problem of the artificial limb which the amputee must wear throughout life. As a result, amputations rarely have been considered from the

There is a great need for closer co-operation prosthetic point of view between the surgeon and the limbmaker Occasion ally and unfortunately surgeons, through lack of information fall in advising the patient as to his per manent prosthesis or in supervising its fitting Few surgeons are familiar enough with prosthetic appli-

ances or limb fitting to give such advice.
There is a definite need for a practical text devoted to the amputation prosthesis Such a text to be of value, should be concerned primarily with principles of fitting and aligning the proathesis and with instructions as to its use. In this book, the surgeon and limbmaker have collaborated combining the scientific knowledge and training of the surgeon with the mechanical skill and practical experience of the limbusker in order to give to the physician and the limbmaker alike a practical manual on the selection fitting, and use of artificial limbs

In the construction of the amputation prosthesis, emphasis is placed on simplicity of design and light ness of weight with durability Materials used are important only insofar as they are light and durable and lend themselves readily to the necessary adjust ments of alignment and fitting. The choice of ma terials often will vary according to the individual needs of the amputee depending upon such factors as the site of amputation and the age, sex, occupa tion, and physical condition of the amputee.

Elaborate and complex joint mechanisms and control, despite extravagant claims of manufacturers and salesmen, are not essential in the average pros thesis. They add considerably to the original cost are more difficult to adjust and repair and offer few If any advantages over the more simple standard types The ordinary amputation proathesis is really a very simple apparatus mechanically, and if it is properly aligned and fitted it fulfills its functions most satisfactorily without complicated mechanisms

Of far greater importance than materials and types of joint mechanisms in the successful use of a prosthesis are the proper dispunest and filling of the This requires considerable skill based on experience and judgment, and a thorough under standing of certain fundamental anatomic and physical standing of certain fundamental standing of certain fundamental anatomic and physical standing of certain fundamental standing lologic principles. Surgeons and limbinakers silke barge principles. Ourgeons and importance arise importance of materials and complex mechanical devices, neglecting the all important principles of alignment and fitting In this text considerable attention is given to these fundamental principles.

Both the surgeon and limbmaker should guard against unwarranted claims and against encouraging Ill founded hopes on the part of the amputee.

One chapter of the text pertains to prostheses for children-a subject which presents certain special problems and which heretofore has been given little or no attention in surgical texts

A chapter is also devoted to the subject of the rehabilitation of the ampute. Particular emphasis is placed on the importance of the emotional readjust ment of the amputee to his handicap. Attention is directed also to the necessity for instruction and training in the proper use of the prosthesis. Vocational guidance and selective placement in employment are also emphasized. Consideration of these problems, so often neglected, are of the greatest importance in the successful rehabilitation of a person handicapped by the loss of an extremit

Special acknowledgment is given to Captain Henry Kersler MC USNR, for use of photographs and diagrams demonstrating his cincipastic amputations and illustrating postoperative care of the stump preparatory to fitting the proathesis, as well as for his valuable contribution on the subject

of rehabilitation of the amoutee

The text covers the following subjects development of modern amputation prostheses the amputation stump prostheses for amputations of lower extremity alignment and fitting of lower extremity prostheses upper extremity prostheses prostheses for children and rehabilitation f the amputee

In comparison with some sidely publicized contributions on the sam subject, the real let will find the present volume a pleasant rehef. The book is remarkably practical throughout. The illustrations are unusually instructive.

PHILE LEWY.

As a result of his deductions from a study of the embryology and comparative anatomy of the stomach the author of The Musical Build and

Movements of the Stomack and Duodenel Bull take that the human stomach consists of four parts. Each part is homologous with each of the four storached ruminants. He suggests that the forsit of the human stomach is bomologous with the rame and the corpus with the reticulum (second storact) These constitute the longitudinal stomets. The transverse stomach which is usually idented to a the pars pylori, beginning at the incisura he dwies into three parts. The "slaus fans out downered from the incisura forming the knee or ellow a the greater curvature. The membrana annihus' fans out upward from the junction of the sne val the pyloric canal, to form a bulge on the lener canature between the incisura and the pyloric cand Thus, the sinus and membrana angulara ion what is frequently referred to as the pylode was bule and the pyloric canal, called the pyloric antrum or "prepyloric region. The droderal bea appears to be correlated with the pyloric spherer, which structure contains a duodenal as well as gastric component

His anatomical description of the arrangement of the muscular fibers in the stomach in relation to the pyloric portion of the stomach and sphericer a

enlightening.

The book is recommended to all students of the anatomy and physiology of the stomach.

Ridley H: Ocular Manifestations of Malnutrition in Released Prisoners of War from Thailand. Bril. J. Opkik., 1945, 29, 613.

The author reports on the unique opportunity offered by the examination of 500 releazed allied prisoners of war and interners from Thailand who believed that their vision had deteriorated during their captivity. Food had been deficient in quantity and especially lacking in proteins, fats, and vita miss. Meals had consisted mostly of polished rice vegetable stow, a small quantity of meat and tea. For a period of 6 months the food had been reduced nearly to the starvation level, with only rice and salt for one period, and it was during this time that most of the visual symptoms occurred. Ninety of 100 patients were amblyopic.

In many cases the amblyopus had occurred during a single day in others the onset was more gradual. Night blindness was uncommon. Camplimetry revealed in 90 cases a small central scotoma not usu sily extending over 3 degrees from the faxtion point, although in the severe cases it was much larger Aboved normal fund, but in others a temporal pailor of the disc was noted. Altogether there were 48 definite and 30 doubtful cases of optic attrobive.

Practically all of the released prisoners showed some degree of keratoconjunctival abnormality usually an increased vascularity at the limbus with the formation of aneutysms, and vessels and opacity extending into the cornes for about a mm. There were 3 cases of interstitial keratitis with negative Kahn testa.

While there seems no doubt of the relationship of the vinal disorders described to the nutritional deficiency the author is inclined not to place the entire blame on a single vitamin deficiency but rather on the general malnutrition of the prisoners. However some of the changes described might well be secondary to deficiency in vitamins of the B group. There was noted a high incidence of arrus sentils in this relatively young age group and this slab suggests a detangement in fat metabolism

Treatment in these cases included a full det and supplemental vitamin therapy. The author plans to offer a later report showing the results which have been achieved. In the severe cases with marked optic atrophy too much improvement is not to be expected. Visual acuity at the time of the original examination varied from 1/60 to a partial 6/6 WILLIAM AMARY MID.

Sen K., and Ghose, N: Ocular Gnathostomissis.

Brit. J. Opkth., 1945, 29 618.

Few cases of parasites recovered from the eye have been reported. The author reports the first case of gnathostomisus in the human eye. In fact, this infection is quite rare in the human being and up to 1937 only 24 definite and 60 clinical cases had been reported and these involved the stomach, large, kildneys, mastod and subcutaneous tissues.

The present instance occurred in a s6 year old Hindu who was admitted to the hospital for investi gation of an orbital cellulitis with hemorrhage in the retina and vitreous of the left eye. He developed an intia and after a considerable period of treatment a moving pigmented nodule was noted in the an terior chamber imbedded in the ins. Slit lamp ex amination revealed it to be a worm.

The parasite was removed after a retrobulbar in jection to reduce the intraocular tension (which had been elevated). After a suitable incision with a thin Graefe knile the worm was removed in tole with a curette. Recovery was uneventful. Later examination showed the disc to be strophic and the arteries thin and sheathed, and there was a pigmented scarbin and sheathed, and there was a pigmented scarbine to the macula. As this was not present on the first examination it was believed to be the point of entrance for the parasite. WILLIAM, MANN M.

Rosen E.: Disbetic Needles. Brit. J Ophth 1945 29 645

The author points out that in dishetics characteristic changes can be found in the lens in addition to the accepted ocular signs of dishetes such as rubeosis iridis, small globular hemorrhages at the macula, retinitis proliferans, retinitis circinata, sudden onset of hyperosia, and licentia retinalis.

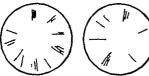

Fig 1 In this case the patient had no knowledge of having diabetes. The vision was 20/100 in each eye, and was correctible to so/30 in each eye. Examination of the ions revealed the presence of diabetic needles. The fundus showed no evidence of diabetes. Urine examination disclosed the presence of sugar

Fig. s In this case the patient was 60 years of age. She had had diabetes for z years. Diabetic retinitis was present especially at the macula. In the periphery of each ens there were several diabetic needles amerimposed upon the includent cortical opacities.

He describes a lenticular sign in diabetics which when present is considered specific for diabetes. It is known as the diabetic needle or "roman numeral" sign-a linear black spoke in the periphery of the lens which is no thicker centrally than it is peripherally. In all cases the spokes were never thicker at the periphery of the lens than at its center and they were seen best with the indirect ophthalmoscope or the retmoscope,

A series of 10 cases which presented these so-called "diabetic needles" is reported. Many of the cases also presented nuclear and cortical lenticular oracities. JOHN TA ZUCKERNAN M.D.

Smeleer G K., and Ozanica, V: The Effect of Local Anesthetics on Cell Division and Migration following Thermal Burns of the Cornes. Arck. Ophik., Chic., 1945 34 271.

Smelser and Ozanica discuss the effect of local anesthetics on cell division and migration following thermal burns of the cornes.

They conclude

Topical application of most anesthetics inbiblts mitosis in the intact corneal epithelium if they are of a sufficient concentration to produce andthesis.

- The inhibition of cell division varies with the drug the method of administration and the faquency of application.
- 3 If aneathetics are applied locally to most burns the migration of epithelial cells over the a jured area is markedly inhibited.
- 4. Most anesthetics also inhibit cell divolonis in regenerating epithelium.
- Some drugs inhibit mitous but do not retail ceil migration. 6 Nupercaine and phenacame ointments prober
- prolonged surface anesthesa, but do not bear mitosis in normal epithelium nor retard cell dicita or migration in regenerating epithelam.
- 7 Unbuffered aqueous solutions inhibit bester more than continents of the same or of grown strength. JOSEPA ZUCKERNAN, M.D.

### Roper K. L.: Senile Braline Scient Flores. Arch Ophik., Chic., 1945, 54 153. The author reviews the literature on a chank

asymptomatic entity be calls senile hysline atmi plaques " and reports 5 cases of his own. There plaques, which are rectangular round, or oral and of a slate gray color are symmetrically should about 3 mm. from the limbus and about 1 #1 anterior to the insertions of the lateral or work frequently of the medial rectus musics. The patches are slightly depressed and translament clearly Patients are generally unaware of the prience of the condition.

Advanced ago associated with dehydration rel progressive scierosis is considered the next per disposing factor in the disease. It probably is det a local nutritional disturbance resulting for arterioscierosis and the stress and strain on the sciens. For this reason the term senile system acleral plaques," is preferred to more conferm

names As far as a differential diagnosis is emeened for author points out that acleromalacia perious primarily necrotic in origin, whereas scient phoare degenerative brawny scientia is an investor granulation there and plasma cells and process deeply pigmented, whereas acteral plaques are par-JOSEPH ZOCKERNIK, M.D. and nonplymented.

### EAR

Hall, I S.: Fenestration of the Labyrinth. I le Otal Lond., 945 60 200.

The author reports his experiences with the feet tration operation for deafness due to otoschoos h 71 cases during the past 6 years. The action operation is essentially the one stage procedur is veloped by Lempert from the multiple star cedure of Sourdille A pedicle flap consisting of the thin skin of the bony posterior and superior sall a the external canal attached to the drum members is preserved to cover the fenestrum. The esting prefers the postauricular mastoid inches to the endaural approach The annulus tympanicus apmoved in the upper portion and the incus and head of the malleus is resected using care to preserve the skin flap attached to the drum in an undamaged state A dissecting microscope is used while working on the labyrinth capsule General anesthesis, con sisting of heavy premedication and light ether is favored since immobility of the patient is desirable when using the microscope. The fenestrum is made ever what is considered to be the ampuls of the hort ontal canal Electrically driven burrs of various ypes are used Important points in the making of he fenestrum are considered to be the use of irriga tion to remove bone dust and the care with which the endosteum and small bone chips are removed by means of small scrapers and needles. Paraffin gauze is used to hold the skin flap in position and is removed after from 5 to 7 days. Skin grafting of the cavity is sometimes carried out at the time of the first dressing by either the Thierach or pinch method The results have shown a steady improvement

over the 6 year period and approximately \$5 per cent of operations during the past year are considered to be successful Revision of a fenestrum which has closed is a more delicate procedure than the primary operation and entails greater risk to the membranous labyrinth. The opinion is advanced that even in cases in which the fenestrum has closed subsequent deterioration of hearing appears to be arrested as has been shown by comparison with the opposite ear Fallure to orient sounds has been noted on several occasions following the fenestration operation but vertigo has not been troublesome after the first weeks

The causes of failure which are commonly met are closure of the fenestra advancing age and the presence of nerve dealness infection, and technical

failure

### NOSE AND SINUSES

Bernfeld, K. The Genesia of Typical and Atypical Cysts of the Nasal Floor Lar Old Land,

The term cyst of the nasal floor, is applied by the author to prominences of the vestibulum of the nose, strated either just in front of or behind the sper thra pyrilornia, extending to the lateral corner of the nasal floor and containing a liquid matter. They are rather rarely encountered. As a result of the author's experience it appears that small soft cushions of the mucous membrane with very little or no contents, are considerably more common. If, in the routine examination rhinologists did not omit the lowest, most laterally situated corner of the nasal cavity formations of this type would not be compressed nor escape attention. The author belleves it may be helpful to clarify the genesis of these

The distinction between typical and atypical peculiar cystic formations. cysts has been made from a clinical and not from a

The diagnosis offers no special difficulty if the cyst genetical viewpoint. is found at its typical site within the soft parts.

Palpation from underneath the upper lip with simul taneous probing will at once clarify the nature of the tumor found there Aspiration yields a translucent yellowish fluid in which usually no cholesterol is

The most important cyst in differential diagnosis is the radicular dental cyst excluded by radiography contained

As long as the typical or atypical cysts are small and cause no symptoms, any kind of treatment is superfluous If however the growth of the cyst suppuration, or some other condition makes its removal imperative the procedure should be a radical one by peroral approach underneath the upper lip The operation should be followed by cauterization

The total number of cases presenting typical which ensures a firm scar nasel floor cysts was 3, that of atypical ones 21 4 of the patients were children (3 girls of 8 11 and 12 years, respectively and 1 a boy of 7) 17 were adults between the ages of 28 and 38 years.

The cysts occurred unlaterally in 13 cases (in 8

cases on the right) and bilaterally in 8 JOHN F DELFH M D

Beck, A. L. Abscess of the Nasal Septum Compil cating Acute Ethmoiditis. Arca. Otolar Chic.

Abscess of the nasal septum may result from in fection anywhere in the neighboring tissues, but such abscesses occur most frequently after accidental or surgical traums. The pus may be found on one side or on both sides of the cartilaginous and bony framework The author reports 2 cases in both of which incision on one side only was adequate

The cartilage apparently disintegrates for frag mentation or sequestration of cartilage or bone is not always recognized at the time of and following surgical drainage Abscess of the septum following trauma is preceded by the formation of a bematoma between the mucoperichondrium and the cartilage. Abscess following sinusitis probably is not preceded by the formation of a hematoma. There was no hematoma in either of the cases reported

Abscess resulting from injuries accompanied by simple and compound fractures of the nasal bones must be a rare occurrence since the author has not observed it over a period of many years Observa tions of persons injured in automobile accidents as they appear in the accident room of the hospital serve as the basis for this statement.

Abscess of the septum has been reported following endonasal antrostomy performed through the in ferror measus. This may possibly result from instru mental trauma to the lower part of the septum in

the performance of the operation. The one unfailing symptom of septal abacess is complete usually bilateral, obstruction of nasal breathing Tenderness, pain in the nasal and orbital regions and swelling of the nose are also present. The mucosa covering the septum does not shrink when epinephrine hydrochloride and other vasocon strictors are applied.

Pionatelli, G : Solitary Naurinoma of the Tonone (Neurinoma solitario della Hosma) Giar tial chie na e

The author describes a solitary neurinoms of the tongue in a patient aged so The condition had been in existence for 8 months. The tongue had a normal color was moist and showed no impairment of its movements. A tumefaction was palnable at the tinof the tongue, this was elastic of rather hard conaustency and was not sharply circumscribed. Pain could be provoked only by strong pressure. The lymph glands were not involved and the Wasser mann. Sarha, and Meinicke reactions were negative.

Various conditions had to be considered in the differential diagnosus Cavernous angioma is easily recognizable by its color and compressibility communitied fymphanesoma is relatively hard and is usually found on the lower surface of the tongue linenal papillae are paually enlarged. Carcinoms or sarcoma of the tongue has a rapid evolution. Fi broma usually has a submucous location but it may be nedunculated. Linoma, as a rule resembles a fibroma clinically but its consistency is softer Synhilis of the tongue in the form of a summa involves the surface of the tongue and shows a tendency toward ulceration. The blood examination confirms the diagnosis. A tuberculous granuloma as a primary manufestation of tuberculosus is very rare as a rule signs of pulmonary or intestinal tuberculosis are present. Actinomycosis of the tongue shows a rapid evolution and the hard nodules gradually become soft and lead to the formation of fiatulas. Hydatid cysts of the tongue are extremely rare and reach a considerable size. Glandular cysts usually have a marrinal location. Conrenital cysts are found at the base of the tongue and in the region of the lineual V

The author removed the tumor under local anesthesia. Its weight was 30 gm. The histological diagnoses was neurinoma. Such tumors originate from Schwann's sheath. Several varieties of the tumor such as neurofibroma or neurinoma sarcoma todes, and neurocytoms, have been described Parallel fibrillae cemented together with a protoplasmatic substance and nuclei located at various helehta are characteristic for neurinoma. location of the neurinoms at the tip of the tongue is very rare. No anatomic connection between the tumor and a nerve trunk could be established Many workers consider the tumors to be hamar tomas or aberrant formations of neuroblastic origin. IONETH K. NARAT M.D.

Shirer J W., and Cohen M: The Effects of Thiouracil on the Thyroid Gland. Ass. Ist. M., 1945, 23 790.

Six hyperthyroid patients were treated with thiouracli for varying periods to prepare them for

thyroldectomy These periods were relatively than from o days to a month, except in a justine h which the thiouracil medication was continued in months. Two of these nations had previous ben prepared with lodine and subjected to a lobertone and the histological picture at the first operation in shown the more or less twoical lodine investigat effects

At the second operation the remaining lobe in a st these patients exhibited the typical hyperplatic thioursell picture, i.e., small empty actor and hi rate aranular cells with large pale central anda, while in the other case the histological pictor w sembled a simple colloid poiter, unaffected by the thioursell except in isolated hyperplatic rather where the typical thiograpii effect was evident in nearly every instance the shad or lobe spound friable and vascular upon removal, so matter sixt the amount or character of the preparation and the postoperative reaction was rather severe cres sepromaching that of the thyrold crais. Nevertheles a I patient, to whom no lodine had been administrati and to whom thiouracil had been given for only to days preoperatively the gland did not specvascular or friable and the postoperative matter was mild, and yet the microscopic picture revealed a typical thiogracil effect in other words, it was me always possible to correlate the clinical and the nathological pictures in this series.

In the case of the patient who had taken thous cli for 7 months preoperatively no mention is made of gland friability and there was no postoperary reaction, the microscopic picture showing a patriy architecture with hyperplastic areas, which was not like an untreated Graves disease than a train thiouracil effect. This was interspersed with less darker celled acini and large masses of colloid, who gave the appearance that the gland was underpite

a colloid involutionary process.

Although it is admitted that thiourses will come trol clinical hyperthyroidism in the patient who has undergone operation as well as in the patient was has not been subjected to it, the authors are of the opinion that lodine is still the drug of choics for preparing the thyrotoxic patient for operation. The opinion is based upon the technical diffication to perienced by the surgeon because of the incress vascularity and friability of the gland shick in been prepared with thioursell, the frequent story postoperative course, and the fact that student have not as yet been set up to determine shee the patient under thiouracil medication is resty for operation.

Many excellent photomicrographic reproduction accompany the original article.

JORGE W BRESCHE, M.D.

Bartals, E. C.: Thiobarbital in the Treatment of Hyperthyroldism. J Am. II Am 1913 LT

Astwood has reported that diethyl thiobarbing acid (thiobarbital) has antithyroid activity mile to that of thiourscil. Experiments on rats showed that thiobarbital in small doses was somewhat more effective in infibiting thyroid function and perhaps less tone than thiourscil. However animals which received thiobarbital in larger doses were found to have fatty infiltration of the liver.

The opportune moment for the author's initial irrial of thiobarbital came in October 1044, when a patient receiving thiouracil developed a lever reaction which necessitated discontinuance of treat ment but further antithyroid therapy was essential before thyroidectomy. This first experience with thiobarbital revealed that this drug has unquestion able antithyroid action in human beings and that semilitrity to thiouracil does not preclude its use.

Throbarbital has now been used at the Lahry Clinic in the treatment of 28 patients with hyper thyroidism and definite and satisfactory anti-

thyroid response was obtained in all.

Of o patients in whom toxic reactions to thioura cil developed 7 tolerated thiobarbital which produced complete relief of the hyperthyroldism

Eight of the 28 patients receiving thiobarbital, or 28 per cent, developed toxic reactions to the dury The depressive change in the white blood cells was the only serious reaction. Two patients developed agranulocytosis. There was no death due to the

drug

The time required to control hyperthyrodism with thiobarbida was found to be the same as that with thiouracil. The antithyroid effect of thiobar bital is apparently twelve times that of thiouracil, since o.o.g m. of thiobarbital accomplished the same rasult that o 6 gm of thiouracil accomplished Since no sade effects were observed with the smaller dose (o o g gm) further studies with this dose seem justified to determine its disincal effectiveness.

The anesthesis and postoperative course of patients treated with thiobarbital is similar to that of the thlourself treated patient. The combined use of the blobarbital and iodine produced satisfactory in-

volution of the thyroid gland

The high percentage of reactions to thiobarbital has led to the use of thiobarbital for only those patients unable to tolerate thiouracil

JOHN E. KIREPATRICK, M.D.

Barr D P., and Shorr E.: Observations on the Trentment of Graves Disease with Thiouracil Ann Int M., 1945 23 754.

Among see cases of thyrotosicosis treated with thiouracil, remission was induced in 87. The drug exerted a beneficial effect on emaciation tremor hyperkinesis, and the circulatory symptoms also on the basis metabolic rate cholesterol levels the creatine defect and on the tendency of thyrotosic patients to kee nitrogen calcium and phosphorus Protrusion of the cychalis was not decreased but lift spam and lift lag were decreased or controlled.

Benefit from thiourneil was often apparent in less than 10 days, and normal conditions were usually attained within 40 days. Factors tending to retard the rate of response were the previous use of lodine and large nodular solters.

Of the roo cases, 73 presented successful results in the sense that the thyrotoxicosis was maintained in remasion. In 37 of the 73 cases, the drug was withdrawn for from 2 to 16½ months without relanse.

There were 3 deaths from circulatory complications, but none could be justly ascribed to the action of the drug. In 12 cases unfavorable symptoms resulted in withdrawal of the drug. Two cases of agranulocytosis were encountered.

SAMUEL KARN M.D.

Snitman M F: Carcinoms of the Larynx Significance of the Histopathological Study of Serial Sections; Preliminary Report Arch Order Chic., 1045, 42–178.

This report concerns itself with the histological study of a block of laryngeal tissue removed by thyrotomy. The block of tissue included about of cm of the anterior end of the right true and false cords.

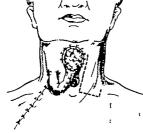

Microscopic study revealed incomplete removal of the cancer in situ of the right true cord. Although the lesion involved almost exclusively the region of the glottic lip of the entire length of the true cord tissue there was no subjective or ventricular extension. The presence of a greater length of cancer in situ anterior to the hornifying carcinoma, and of only a small amount posteriorly caused the author to conclude that the lesion grew to the anterior commissure and extended to the opposite cord.

A true picture of the laryngeal pathological changes could not be determined from the original specimen. It is believed that serial histological studies of laryngofissure specimens would prevent delay in the management of residual malignant mooplestic tissue. Noar D Farancart M.D.

Ivanisaerich O and Ferrari R. C 1 The Treatment of Extensive Pharyngostomies following Laryn gectomy (El tratamiento de los graedes farinçostomas consecutivos a la laringectomia) Bol Inst clin quir B Air., 1945 st 186

Before the development of the modern technique extensive pharyngectomy following laryngectomy was frequently necessary because of necrosis and infectious processes heal spontaneously or the remaining small fistulus close following minor surgicular procedures. However in a certain number of cases infections or necrotic processes produce an extensive pharyngostomy especially if a large portion of the anterior aspect of the pharynx persites. Fortunately such cases are rate.

As a rule pharyngostomics develop in patients irradiated prior to the operation because the connective tissue undergoes certain changes. Because of such changes in the aurrounding tissues a repair of pharyngostomy is very difficult and disruption of the wound is the rule rather than the exception

Second stage of the operation.

In 4 cases the authors succeeded in reconstructing the pharynx by using a tubular cervicothoracic flap When the suture line of the tube formed a scar the circulation at the distal end of the tube was inter

rupted by the application of an elastic forest in gradually increasing periods of time. When a the surgeon s opinion the blood supply to the tale facthe proximal end was sufficient, the lower end was severed and the so-called delayed flap was placed is proper position to cover the defect in the planter. The proximal end of the tubular flap was placed in the vicinity of the pharyngostomy while the barr end of the tube was placed below the davids mi more to the side than the proximal end. To one the defect, the dastal end of the tube was turned at ward and the upper portion of the tube was ac-tioned. The defect which was produced by form tion of the tubular flap was closed with interrested autores.

Another rectangular flap was prepared from the opposite side of the antenor aspect of the neck, viti, the base at the level of the defect in the plants. The flap was rotated oo degrees so that histered at pointing downward, it lay in a horizontal direction The defect created by the change of the position of the rectangular flap was covered by a translatition of a free flap from the subclavicular report Chromic catgut was used for suturing the tabler

flap to the pharyngeal wall.

# SURGERY OF THE NERVOUS SYSTEM

### PERIPHERAL NERVES

Sunderland, S.: The Blood Supply of the Peripheral denand, c.: Live phoof dapply of the Leaping and Nerves; Practical Considerations. Arck. Veur Psychial Chic., 1945 54 180.

Free and extensive mobilization of the nerves, often required in peripheral nerve surgery necessiotten required in perspired nervolve which tates the division of many arterize nervolve which bind the nerve to an accompanying arterial channel. The sacrifice of many nutrient vessels fortunately does not seriously jeopardize the nutrition of the nerve. Nerves are abundantly vascularized the anastomoses are numerous, and there is considerable overlap of supply Experimental work has shown that the collateral circulation of a nerve is efficient even when the nerve is freed from the surrounding tissues over a considerable distance.

The author suggests the preservation of the super ficual longitudinal vessels which lie in the epineurium and anastomose along the course of the nerve and advices ligation and division of the nutrient vessels some distance away from the nerve in order to preserve the vascular anastomoses. Furthermore

Fig 1 Superficial blood supply of the peripheral nerve-

should a large nutrient vessel be torn or divided at the surface of the nerve it may retract into the epi neurrum and cause troublesome hemorrhages which result in damage to superficial nerve fasciculi and the formation of an undesirable scar

Grouge Person M.D.

### BRAIN AND ITS COVERINGS; CRANIAL NERVES

Eaglesham D C.: Radiological Aspects of Intra cranial Pneumocephalus Bril J Radiol., 1945

The author states that head injuries may lead to the introduction of air into the cranial cavity and he discusses its occurrence in 22 cases observed at the Basingstoke Neurological and Plastic Surgery Hospital R.C.A.M.C from July 1942 to April,

The great majority of cases occur in conjunction with fractures through the accessory air sinuses. Nontraumatic pneumocephalus may result from erosion through the paranasal sinuses of a tumor or an infective process. Although gas producing organ isms may be introduced into the cranial cavity with a resultant formation of gases these are considered essential to the discussion especially with regard to the differential diagnosis. Two examples of this one quiestential diskinosis. Two examples of this condition are given in which the underlying pathological process was cerebral abscess

The radiological points favoring gas producing cerebral abocets as contrasted with other causes of pneumocephalus, are (1) the gas is remote from the purcumocephanus, are (1) the purcumocephanus, i.e. the accessory usual source of pneumocephanus, i.e. the accessory sinuses (2) multiple gas pockets are close together and (3) a larger space-occupying effect than the amount of gas would suggest with a pineal shift.

Points favoring intracerebral pneumocephalus rather than gas producing abscess are (1) the presence of gas in the subarachnoid or subdural space in addition to that in the cerebrum, and (2) a rapid appearance or a rapid increase in the amount of gas seen. This, for instance may sometimes occur in traumatic pneumocephalus if the patient blows his nose

Porencephaly may also be confused with pneu mocephalus after an encephalogram has been made. In porencephaly the ventricular shift, if any is to the affected side more gas is seen than was considered to have been introduced the gas pocket is at a distance from the accessory sinuses and there is persistence of the gas pocket after the air is absorbed from the ventricles and the subarachnoid space. Intra cranial lipomas may give a certain radiotranslucence but less than air or gas and in the case of the latter there is not any calcification at the margins. On occasion air introduced accidentally at lumbar puncture may appear in the cranial cavity

From the standpoint of radiological technique, stereoscopic views are always necessary to determine the extent of the shadows. An attempt should also be made radiologically to determine the source of the gas. This involves a study of the nasal and mastold sinuses, with special reference to the cribriform

All of the cases under discussion were of traumatic origin. Only 6 were due to gunshot wounds, the others being so-called closed head injuries which occurred in road accidents. The total number of patients with gunshot wounds, from which the 22 cases were culled, was 814. In some cases the exact origin of the pneumocephalus was not found. Four patients developed meningitis. When the possibility of pneumocephalus exists, radiological re-examina tion may be necessary from time to time.

ADDRESS VERBEDOGRESS MLD

Rodriguez, B., Barrios, R. R., and Oreggia, A.: A New Type of Pedunculate Syndrome. Anterior Nuclear Ophthalmoplegia and Bilateral Cerebellar Syndrome Caused by Teamental Lesion (Un nuevo tipo de sindrome peduncular Oftalmolejía internucieur anterior y sindrome cerebeloso offateral por lexions tegmental) Arch. arug med., 945 7 353

The author reports the clinical history of a 62 year old woman who developed a vascular syndrome of the mesencephalon. The area of softening was located in the peduncular tegmentum. The clinical picture, which had a sudden onset, comprised two groups of disturbances paralysis of the associated ocular movements of a very peculiar type (anterlor internuclear ophthalmoplegia) and a bilateral cerebellar syndrome with dysarthria. In the early stages of the disease there was also a hemiplegia which receded rapidly. Several signs pointed to the involvement of the postenor longitudinal bundle The motor inco-ordination comprised hypotonus, hypermetria, asynergia, and adiadokocinesis.

The authors consider the lesion as belonging to the mesencephalic syndrome and they propose the name of oculocerebellar syndrome caused by a termental lesion. JOSEPH E. NARAT M.D.

Worth, L. H.: Staphylococcal Leptomeningitis Treated with Intraciaternal Penkcillin. Longs. Lond. 1945 449 634-

The author presents the case of a soldier who was admitted to the hospital with a diagnosis of epilepsy A lumbar puncture was done. Ten days later the site of the puncture was found to be infected and an interspinous abscess was opened. Penicillin was given intramuscularly preceding and following the operation, but no benefit was observed.

Almost a months later the patient was again operated upon. At this time an extradural abscess was found and drained through a small laminectomy opening After a period of 4 days obvious leptomeningitis was diagnosed. Another laminectomy with removal of all dead bone, was done. A pocketed

extradural abscess was drained. Cisternal produce revealed cerebral fluid with 11,000 white cells and definite staphylococcus aureus on culture, Large doses of penicillin were given by the cisternal and and the patient recovered

The author reviews the experiences of other is dividuals who have used penicillin either introve-tricularly or disternally. He believes that the coternal route of administration offers adviation over the lumbar route in pyogenic meningen, and discusses the reasons for this.

PAUL MINIEZ, M'D

Blumenfeld, C. M. and Gardner W J.: Di-seminated Oligodendroglioms. Arti. Jam. Psychiat Chic., 1945, 54. 174.

The authors present a case of oligodendroglass which was disseminated throughout the vestrale and in the leptomeninges. The patient was enamed over a period of 14 years during which he madewent a craniotomy twice. At the age of 17 he developed headaches and petit mal-like attacks ad showed signs of dyspitultarism with routers logical evidence of a pituitary gland tomor. Escephalography revealed a dilatation of both himi and the third ventracles, and at operation a thick ened arachnold was found in the remon of the optic chiasm The patient continued to have bests to and attacks, but lost many of his hypopitalization characteristics. Skull films made at the age of the showed calcifications in the tips of both interior horns and in the left posterior horn of the later. ventricles. At the age of 31 he developed to vulsive seizures staxis, hypotonis, and had a in lateral optic nerve atrophy He was then reoperated upon, and a cystic tumor was found posterior and superior to the optic chiasm. The patient died, and at autopsy a tumorous growth was found plasters on the walls of all the ventricles, the aquedut of Sylvius, and the leptomeninges in various area The main portion of the tumor apparently each ated in the hypothalamic region and lad misquently destroyed it. Histological studies proof the tumor to be an oligodendroglioms and to lare undergone mucanous degeneration.

Eleven other cases reported in the literature is which an oligodendroglioms had become deseminated through the cerebrospinal find patient) are discussed and furnish a basis for the opinion that oligodendrogliomas may be pelther as localized as as slow growing as is usually thought

GRORGE PERSON, M.D.

Christensen, J. C.: Tumors of the Third Ventula.

Personal Experience in 5 Once. (Tumors of invor ventriculo)

Bel. Sec. cirs; Cerleis, 1985 286.

The author realises that conclusions draws by him from his experience in 5 cases cannot be grant

ized without a chance of error In one case the tumor of the third ventricle coexistent with an astroblastoms and tuberos acterosis, while in another with an isomorphous glioblastoma, a lymphangioma of the neck, and multiple nevi An intracranial hypertension without major focal symptoms was characteristic for the entire series of 5 cases. In 3 patients paroxysmal attacks were due probably to a transitory blockade of the circulation of the cerebrospinal fluid either in the region of Monroe's foramen or in the cavity of the

The clinical examination revealed disturbances of third ventricle. the ocular motility hypotonus, and binasal hemi-anopais in all cases hypothalmic and mental symptoms were particularly marked in 1 case but were present to a lesser degree in other cases. In I patient a premature puberty and obesity appeared at an age younger than 10 years, immediately follow ing the extrepation of the tumor One patient developed a moderate obesity of adiposogenital charac

In 3 patients an exact diagnosis has been made on ter after the operation. the basis of ventriculographic findings while in the remaining cases encephalography was employed.

In all cases the right transfrontal approach has been used. This type of approach is suitable for removal of all tumors of the third ventricle except those located in the posterior part.

Ventricular drainage according to Dott a tech nique should be employed if a connderable time clapses between ventriculography and the operation or if the surgical procedure is performed in two stages. The drainage should also be employed during and

Only I death could be attributed to the operation immediately after the operation. The author considers operative results in tumors of the third ventracle as satisfactory One year after the operation 3 patients were in a good condition while the fourth noticed a recurrence of the symptoms 3 months following the surgical intervention

## SPINAL CORD AND ITS COVERINGS

Rocca, E. D. and Valladares, H : Injuries of the Spine (Traumatismos del raquis) Arck. Soc. Cirsjenos Hesp Santiago 1945 15 636

The authors report 25 cases of various spine in juries, reviews the mechanism of various lessons, and describes their symptomatology and treatment. Dislocation occurs most frequently in the cervical region, mostly between the atlas and the axis or be-

tween the fifth and sixth cervical vertebrae. In the dorsal region a dislocation is observed most frequently between the cleventh and twelfth dorsal or between the latter and the first lumbar vertebra Dulocations of the lumber spine are rare on account of the firm fixation of the vertebrae.

Fracture-dislocation may be followed by a tear of the venous plexus located in the epidural space, with resulting hemorrhages on the anterior lateral or posterior aspect of the spinal cord. Blood may accumulate in the epidural, subdural or subarach noid space and this may be followed by intraspinal

hemorrhage with a subsequent development of arachnolditis. One of the authors cases illustrates

The most frequent site of fractures of the spinal such a condition. apophysis is the thoracic or cervical portion of the

A fracture of the vertebral arches involves the atlas or the axis in a great percentage of cases.

Fractures of the vertebral body are caused nearly exclusively by an indirect trauma. In this type of fracture a medullary shock or concussion of the spinal cord is frequent and may produce a physiclogical section of the cord with a grave prognosis

Fracture-dislocations of the spine are produced in a great percentage of cases by indirect trauma caused by a hyperflexion or hyperextension.

Injuries by missiles may sometimes create a picture of an anatomic section of the spine while in reality only a physiological section is present. The authors describe I such case in which a projectile produced an irreparable physiological section of the

The degree of disintegration of the white or gray substance of the cord after a concussion depends on the intensity of the nutritional disturbances. This fact explains the appearance of medullary symptoms weeks or months after the trauma

Medullary lesions may be situated at points distant from the site of trauma. For instance, 1 of the authors patients sustained an injury of the dorsal region of his spine and yet the resulting myelomalacta involved the entire medullary tract Hematomy elia or intramedullary hemorrhage, which may be produced by any type of trauma, affects the cervical portion more frequently than any other region of the spine. The original trauma may be transmitted through the column of the cerebrospinal fluid and cause hemorrhages in the gray sub-

Surgical intervention is indicated in the treatment stance at distant places. of spinsl injuries (1) if compression of the cord is demonstrated by the Queckenstedt test, stereoscopic roentgenograms pneumospinograms, and myclograms, (2) if after a favorable evolution neurological symptoms of compression indicate that scar tissue is the responsible factor and (3) if symptoms of compression appear following orthopedic

The authors employ local anesthesia for interven tion on the spine in all cases with very lew exceptions. Tidal irrigation is recommended for the treatment of the cord bladder supplemented by the administration of sulfa drugs administration of sum orthopedic surgeon and collaboration between orthopedic surgeon and neurologist is stressed JOSEPH K. NAEAT, M.D. neurologist is stressed

Guthkelch A. N: The Management of Recent Fracture Dislocations of the Cervical Spine. Bril M J., 1945 2 880.

In fracture dislocations of the cervical spine with cord symptoms, Crutchfield tongs may be applied and the patient may then be nursed in the sitting

position This is the main point set forth in the present article. Seven cases were treated in this way with satisfactory results. There were 4 deaths but these occurred in complete transverse lesions of the cervical cord and the lesions could be regarded as incompatible with life from the beginning

The method is simple and can be applied any where A stout post is lashed to the head of a bed and a pulley is fixed to it the tongs are applied in a line slightly anterior to the pinna a back rest is elevated until the patient is raised up to an angle of 60 the tongs are weighted through the pulley with 18 pounds. Portable x ray pictures are taken in half an hour and if there is no radiological change 4 pounds are added \ ray pictures are taken every half hour and weight is added until the dislocation is reduced. When this happens, from 8 to 12 pounds of weight are applied and maintained for at least 3 weeks then the weight is further reduced for 10 days and the patient is allowed up in a plaster cast.

The sitting position has several advantages (1) gravity is used for traction (2) the upward thrust of abdominal viscera is avoided and this is important in patients who have respiratory difficulties, and (1) the patient is able to look around swallow properly and read These factors promote better results than can be obtained in the usual lying position and they improve the morale of the patient.

ADMICS VERRIOGOREM, M.D.

### SYMPATHETIC NERVES

Wilson, H.: Thrombosis of the Brachial Artery Treated with Successive Cervical Sympathetic Blocks. Am. J Surg 1945 to 155.

Blocking of the sympathetic chain is useful in the treatment of occlusive vascular disease, both of an acute and chronic nature. In thrombosis of a major vessel there is spastic contraction of the collateral channels which further decreases vascular supply to the part. Sympathetic block will relieve such spasm.

A case treated by such a procedure is presented The patient was a so year old soldier whose right arm was pinned to the ground for 30 minutes as the result of an accident. He had a fracture of the left clavicle and contusions of the right chest wall and arm and of the face. The arterial pulse could be felt above the point where his arm had been pinned but not below The right hand was cool and moist the sensory and motor functions in the right arm were both greatly reduced. Since no hematoma was present, it was thought that the patient had a severe spasm of the right brachial artery Three hours and twenty minutes after the accident a right cervical sympathetic block was performed with a per cent procaine. The results were inconclusive Five suc cessive blocks were performed at intervals of approx imately 3 hours. The hand and arm were warmer after each block, but the effect usually disappeared In about \$36 hours.

After 7s hours a weak radial pulse was felt, but this disappeared a days later. Sensation became normal, but the patient had only 50 per cent med the intrinsic hand muscles.

Four weeks after the injury the radial poke an still absent so the diagnosis was changed to time bosis of the brachial artery rather than spena

Procedures now in use in arterial intures in the ligation of a partially severed artery with its cacomitant veln followed by sympathetic process block. Blakemore s nonsuture method of briens the arterial defects is occasionally used but a three bosh or blowout may occur later A procedure some times recommended is resection of part of an arter to interrupt the sympathetic supply dirtil to the resection. However sympathetic block is end-remore complete. The author favors repeated pecaine blocks rather than alcohol became of the sc casional occurrence of complications such as an or neuritis which follows the use of the latter.

The deleterious effect of applying external ket a the affected extremity with the resultant increase

oxygen demand is also stressed.

ROBERT E. GREEK, M.D.

### MISCELLAREOUS

Wolf G A., Jr., Goodell, H., and Welf, H. C. Prognosis of Subarachnoid Hemorrhage, J As M Ast. 1045 180 7 5

In order to formulate a plan of management of patients with spontaneous subarachnoid benoring the authors studied a group of 46 patients from the New York Hospital. The diagnosis of a selandnoid hemorrhage was verified either by postmorten examination operative visualization, or the foliage of zanthochromic and bloody spinal field. There were no differences in sex distribution. The greates number of cases occurred in the fifth decade, the cases being twice as common as at any other pered

Fifteen per cent of the patients had a prener history of migraine headaches, while so per and last noted recurrent headaches. It was noted that the majority of patients were engaged in ordinary activ ity at the time of the rupture and a history of precapitating factors could not be elicited.

It was impossible to correlate the sign and resp toms with the prognosis-either immediate or lite It is of interest that many of the patients whe had recovered had lost consciousness and had carri sions at the onset of the illness. Eleven postnortes examinations demonstrated ancuryous in 5 cast, but no demonstrable source of beeding could be found in 6 of the cases.

By reviewing the current literature and their ers series the authors promulgated the followed per centage probabilities with the first episode of beet ing so per cent of the patients entering the lover die of the survivors 14 per cent die from recures bleeding between the second and fourth with par another 5 per cent die within one year Based upon the previous probabilities and set

cal mortality rates, an excellent management pot

has been formulated.

I Within the first or second week the surgical rak of craniotomy is worth while if the general consists of the patient is satisfactory bleeding has supposed and he ancuryam has been verified by a strainer than the satisfactory of the satisfactory

not used.

2 If after a period of one month there are persistent or residual signs or symptoms artengraphy should be done. Surgery would depend upon visual teation of the aneurysm, its atte, and the status of the patient's general and neurological condition.

If the patient has no signs or symptoms directly in the patient has no signs or symptoms directly terable to the aneuryam after the first month retriography and surgery are optional since the negical mortality at the present time is higher than ungical mortality of conservative treatment. Migraine the mortality of conservative treatment and the mortality of conservative treatment in the mortality of present, should be carefully treated head after the because of the possibility during the medical regime because of the possibility of the mortal decay of the aneuryamal wall from refuter to the same of the same of

peated vasodilatations.

H M and Goldberg Kennedy F, Somberg H M and Goldberg B, R.: Arachnolditis and Parsiyals following Spinal Anesthesia J Am If Arr 1945 129

The authors review many of the sequelae which have been reported following spinal anesthesia, and which involve the nervous system. These symptoms comprise stiflness of the neck, involvement of the revenue for the reck, involvement of the revenue for the

severe neurits septic and aseptic meningitis, arach robiditis, neuritis of the cauda equina and other

onditions

### SURGERY OF THE THORAX

### CHEST WALL AND BERART

Duany N. P.: Etiological Consideration concerning Cancer of the Breast (Considerationes etiokelosa sobre el Cáncer de la mama). Arch C house Cancer Habana, 1045 4 121

Up to rose it too maliment tumors and 6 coo benish lesions were treated at the Radium Institute in Havana. One thousand and twenty three na tients had tumors or other lesions of the breast. among them being 1 262 malignant and 462 benion tumors. Of 1 262 patients with malignant tumors 1 248 were women, and of 463 patients with benign lesions, 457 were women. Among the benish lesions the following were observed in descending order of fremency fibroadenomas chronic mastitis or functional hyperplasia, cratic mastitis suppurative mastlita, papillomas, schareous cysts, and ownersmastia

Cancer of the breast was exceeded in frequency only by cancers of the uterus, oral cavity and skin.

Cancer of the breast occurred with greatest frequency in the sixth decade of life, to be followed by the fourth fifth and eighth decades in which cancer occurred with anoroximately equal frequency. Then in descending order of frequency were the seventh. ninth, tenth, third, and second decades, other ages accounting only for a very small number of cases

Seventy-eight per cent of the natients with cancer of the breast belonged to the white race 10 per cent were negroes, and 13 per cent were of mixed race. The entire population consuts of 74.4 per cent of white people and as 6 per cent of perroes and those of mixed blood

In the author's material cancer of the breast occurred three times as often in multiparae as in nulliparae.

The relation between trauma and the development of sarrooms can be established much easier than that between trauma and the development of can

In the author's material cancer was found in the nations a mother or father in only a a per cent of the total. Apparently such antecedents are of no great

importance.

The term mastitis, used by older pathologists apparently means nothing but hyperplasia gradually developing in women over 35 years of age. The term "mastitis should be applied only to an in flammatory process. Evidence of such acute and chronic lesions was found by the author in only a small percentage of his material.

He concludes that apparently no relations of any importance exist between inflammatory processes

and cancer of the breast.

A hereditary tendency toward cancer could not be definitely confirmed by the author's observations. JOSETH K. NABAT M.D.

TRACHEA, LUNGS, AND PLETEL

Crafoord C., and Underen, A. G. IL: Moren ed Salivary Gland Tumors in the Branch at Traches. Acta chir scand, 1047 or die

The authors material of so-called brooks) at nomas comprises 14 cases, the tumors being looked to the bronchi in a cases and to the tracks by

These adenomas were demonstrated in below a the group of mucous and salivary shad topon rel like such tumors in other locations, they may be classified as benien semimalument (klasson, Restriwall) and malienant. Of this series a were bones. s semimalionant, and a malienant.

The classification of the tumors in oscilos mucous and salivary rland tumors evolains both the clinical course of the cases and the biological circ-

acter of the fumors.

Tumors of this kind are generally begin, in sometimes they display signs of a certain local interlogical mallenancy by producing infiltration and destruction and by causing metastases. Horoca, the degree of maliemancy generally specan is it

The authors believe that these tumors should be radically removed, if technically possible, as & a difficult to determine their malignancy or semalignancy histologically in excised material. It is known fact that so-called seminallment mores and salivary gland tumors can occarionally change is decidedly malignant tumors in the course of inse.

Abbott, O. A., and De Oliveira. IL R.; Spontages Pneumothoraces Occurring in Patients Cologoing Peroral Endoscopy J There. Ser 1905

There are many common complications of irra choscopy such as the danger of direct injury to the bronchus and underlying vessels, the dangers atten ing local or general anesthesis, and the occurrence subglottle edema. All too little attention has less paid to pneumothorax as a bronchescopic band

Kahler Soulas, and Benjamim have reported instances of pneumothorax or subcutances physema following trauma to the broachts pro which occurred while attempting the removal of foreign bodies. Here the mechanism of the leaber of air into the mediastinum is evident.

The authors are chiefly interested in the our rence of pneumothorax following diagnostic points endoscopic examination. Examination of the little ture revealed only I case similar to the cases reported

in the authors series.

Spontaneous pneumothorax most comment is attributed to the rupture of a subplema taberran focus. Other causes are pueumonia, palmonto gangrene bronchlectasis, hing aboves, foreign bay

empyema tumor congenital cysts, and pulmonary emphysema. Perforating injuries to the chest wall or injury from within the bronchial tree by sharp objects or instruments obviously may produce

Pneumothorax following bronchoscopy may be due to direct injury to the visceral pleura by the pneumothorax. bronchoscopist. However as these patients have duested lungs spontaneous pneumothorax may occur without endoscopic examination. Thoracic surgeons who use the bronchoscope on patients will most likely make periodic fluorescopic examinations and discover unsuspected pneumothoraces. A ma jority of cases have sufficient pleural adhesions to minimize symptoms complicating the pneumothorax. This, unfortunately does not always occur and the complication may lead to dire results unless

The incidence of this complication is uncertain one is familiar with it. since routine fluoroscopies are not done following bronchoscopy The authors 4 cases of pneumothorax following bronchoscopy occurred during a period of 12 months during which 537 bronchoscopic examinations were made on a surgical chest service for disgoods or therapy. No bronchescopic examinations were carried out for the removal of

The authors present 6 case reports In none of the patients was there any evidence of direct injury to ioreign bodies. the major bronchi. In a cases the pneumothoraces occurring coincident to bronchoscopy were asymptomatic and were accidentally discovered by fluor oscopy In spite of the fact that both patients had suppurative lung disease, no empyema occurred In I case the pneumothorax probably was due to the rupture of an emphysematous bleb since these are occasionally associated with patchy atelectasis in children. A similar etiology was suspected in an

In the third case a pyopneumothorax developed secondary to rupture of a weakened necrotic area of other case. a peripheral abscess. This is a spontaneous phenomenon which is likely to occur in these cases. It is a hazard of the coughing paroxyam subsequent to endoscopic manipulation rather than a complication

The fourth patient had advanced tuberculoss and far advanced pulmonary emphysema Either or of the procedure both etiological agents may have played a role during the postbronchoscopic coughing paroxyams. The fifth patient had no postbronchoscopic

pneumothorax, but died as a result of bronchoscopy and the associated coughing attacks. Possibly the explanation may be that in pulmonary emphysema, compression stenosis of the traches may account for dyspnes with coughing attacks however the true

The sixth case described is rare and may be used explanation remains a mystery to support Hammen's theory that spontaneous mediatinal emphysems may advance to the production of a pneumothorax. Two explanations have

stitual bands of connective tissue to the pleural sur face of the lung which ruptures (2) the air in the mediasthum achieves sufficient tension to rupture the thin mediastinal wall into the pleural cavity Most evidence seems to support the second route as

Pneumothorax has many serious dangers attend ant upon it, and a consciousness of this complication the most likely in association with peroral endoscopy should prove ROBLET R BIGELOW M.D.

lifesaving in some instances.

Melick, D W and Spooner M i Experimental Hemothorax. J Therac Surg 1945 14 461

Experimental evidence is presented in support of the theory that blood coagulates normally in the pleural cavity Blood introduced into the pleural cavities of dogs congulates normally Both the liquid portion of the blood and the clot are readily absorbed The liquid portion disappears within from notice the inquire position ansappears within room to to 14 days and the clot decreases in size to such an extent that it may be overlooked. After a weeks have elapsed little evidence remains to show that blood had previously been present in the pleural

Burlord, T. H., and Burbank, B : Traumatic Wet Lung J Thorse, Surg 1945 14 415

In all wounds of the chest the lung tissue reacts to a greater or lesser degree according to the sever ity and type of the lealon, to produce more than its normal amount of interstitial and intra-alveolar fluid. The bronchopulmonary tree not only has more fluid of which to rid itself but also becomes nore fluid of which to rid itself but also becomes less capable of doing this. The result of these fac tors may be called the "wet lung" of trauma. On tons may be comed the wet times of trauma. On the degree of "wetness and on its recognition and treatment depends the outcome in many cases.

The primary phase of this syndrome finds the patient apprehensive. Dyspnes, accompanied by paroxysms of painful cough, is present. The cough however does not serve to empty the bronchopul monary segments. On examination there is found restriction of motion of the involved side with diminished breath sounds. The outstanding feature is the presence of rales bilaterally but more marked on the affected side. In some instances the patient appears to be having a typical attack of bronchial asthma. In many cases the condition resembles nontraumatic pulmonary edema.

Recognition of the presence of wet lung" should not detract from the importance of other lesions which may be present. The necessity for the proper treatment of these lesions must be stressed

In treating "wet lung' the aim must be to control the preduction of mosture and to promote adequate bronchial dramage. Since pain originating me the traumatized thorace cage structure, at the est important factor in the development of the unfavore able cycle of events, and since the pain interferes seriously with an effective cough mechanism the pain must first be combated. The use of morphine and adhesive strapping is physiologically unusued and ineffective. The use of precaine injections, either at the site of injury by intercostal nerve block, or by thorace paravertebral sympathetic nerve block gives gratilying results which are often directive.

While the abolition of pain and the reinstitution of a painless, effective cough mechanism are essential, other forms of therapy are often also necessary. The bronchopulmonary tree may be flooded. The secretions should be mechanically evacuated by tracheobronchial catheter aspiration. In some cases, atropine given intravenously may be of value. In the more resistant cases, oxygen, delivered at a positive pressure of from 6 to 8 cm. of water is of ben

Traumatic "wet lung" must be differentiated from bronchial asthma, pulmonary edema of cardiac origin, pulmonary edema seen in peripheral vascular failure, and from blast lung Samuri Kann M.D

McDonald, J. R., Moersch, H. J., and Tinney W S.: Cylindroma of the Bronchus. J. Thorac. Surg. 945 14, 445

Six cases of cylindroms of the lung are reported. The clinical course was remarkably similar to that of adenoms of the bronchus, with the exception that in a case the neoplasm involved the traches. The bronchoscopic appearance of the tunn also was similar to that of adenoms of the lung. The lung which is the seat of a cylindroms grossly resembles that in which an adenoms is found in that bron chiectass and lung abscass are common sequelae to the long-standing obstruction produced by the time or Cylindroms histologically presents a different appearance from that of adenoms of the bronchus and seems to be more closely silied to mixed tumors and seems to be more closely silied to mixed tumors.

Valle, A. R., and White M L., Jr t Penicillin in Pulmonary Resection J There: Surg. 945

Pulmonary resection in recent years has become a refined surgical operation with a mortality which is comparable to that of the major abdominal procedures. This development is due to (1) lacreased knowledge of thoracic physiology and pathology (2) progress in anesthesia, (3) increased knowledge of shock and fluid and blood replacement, (4) in creased knowledge of the surgical anatomy of the lungs, and (3) developments in chemotherapy Chemotherapy the most recent development, is contributed to the control of infection of the pron chymat, plearn, and their will. For the list 5 year the sullocamides have controlled potential procuronais and disministed plearn infections. It discovery of penicillin opens a new field in the roll of postopentive plearn infections. When Nicholson, and Stevenson, and D Abre, Lacking, and Scott have all demonstrated the porton value of penicillin in controlling plearn infection. D Abre and his coworkers have above his tended for a long as 3 days wille, conversely its passage first the blood stream into the plearn cavity is saght. In creent article Blades reported that the holden of empyema in a penicillin-protected and own series was about the same

In the present article, the authors compar is course and results in patients with pelanousry a section who were treated with and without its administration of penicillin. The authors dense their technique of pulmonary reserton and strastic problem of drainage and the method of osing be

penicillin.

Preoperatively for a or 3 days, 10,000 with a penicillin were given intramuscularly every flows. This was usually continued postopentively for a 4 days, and over a period of 7 days in kerrity or a minimated cases. Fifty thorsand units of pecific in 10 cc. of sallne were injected into the piral space through a catheter at the completies of the operation. For 6 or 7 days after operation, you units of penicillin were injected daily into its pleural space through the catheter or (after reserved) of the catheter of (after reserved).

This series consisted of 43 consecutive pulmony resections carried out during a period of 31 section the first 25 without penicillin, and the last or silvent penicillin therapy as described. The two pears were roughly similar as to diagnosis and opening

procedure.

In group 1 (without pencellinis of, the state of lobectomies and 3 pneumonectomies, 15 were for bronchiestais, 4 for enemoting 5 for long abscess, and 3 for cyate there were for procedured to the pneumonectomies were for carefords as in far across. Mineteen of the 15 cuts of the

sedered as contaminated.

In group a their were 15 lobectomies and 5 per immorectomies of the pneumonectomies, 3 were instructional of the pneumonectomies, 3 were instructional of the 15 lobectomies, and 1 for telescape tools of the 15 lobectomies, 11 were for breaker tests a for telescape tools, 1 for palmonary of the 15 lobectomies, 11 were for the 15 lobectomies, 15 lobectomie

inated pleural spaces.

In group 1, two of the pneumonectories or uncomplicated, the third patient developed is broachial faintiles with a fath empress. Boards faintiles developed in 10, or 40 per cent, of the principle of the

with pneumonectomy and all patients with lobec tomies developed empyema. Tubal drainage for an

average of 12 weeks was required

Of the pneumonectomies in group 2 all patients had uncomplicated recovenes. Of the lobectomies, none of the patients developed a bronchopleural fistula and only I patient developed an empyema.

Fourteen per cent, or 4, of the patients in group I developed chest wall injections while no case in

The patients in group 2 showed a marked decrease group a was so complicated in days of hospitalization and an earlier day of rhing after operation. The average febrile reaction was slightly less than that of the patients in group I

Aspiration of the chest in group 2 patients on the first postoperative day yielded from 400 to 500 c.c. of fluid. The quantity decreased rapidly and thoracentesis was seldom needed after the seventh day Except for empyema in 1 case all cultures were negative. This was in marked contrast to the com

Three of the patients in group I died-one of mon empyemas in group I these (who had had a pneumonectomy) from an empyema due to a bronchial fistula, another as the result of a tuberculous pneumonia and the third patient, from a suppurative pericarditis secondary to a small basal empyema. One patient in group 2 died as the result of an extensive tuberculous apread

The authors discuss in detail the single case of empyema in group 2 which represents a cure of empyems with penicillin, and without surgical drainage An interesting case of lobectomy (group 2) in which pus was spilled into the pleural cavity is also discussed Here in spite of extensive gross contamination no pleural or chest wall infection

The authors attempt to show the advantage of using penicillin intrapleurally and intramuscularly in pulmonary resection without drainage of the space. They believe that the evidence points to protection of the pleural space from infection by pen cillin Blades reported that 11 of 29 patients who were treated with penicillin developed empyema The difference between these figures and the authors figure of 1 case in 20 probably can be explained by the fact that the authors do not drain the pleural space even for a few days therefore a high concen tration of pencillin can be maintained by daily

Successful bronchial closure is important, but it is not the only factor to be considered in the prevention of empyema. The authors believe that an empyema may contribute to the formation of a bronchial fistula. By maintaining pleural asepsis and maximum re-expansion of the remaining pulmonary tissue, the chances of bronchial fistula are lessened

The clamped-off catheter left in the pleural space serves as a simple means of aspirating fluid during the 48 hours when the patient is most uncomfort able. Its advantages are that the penicillin concentration intrapleurally is kept as high as possible Secondly it facilitates the re-expansion of the

remaining lung by the negative intrapleural pressures induced and maintained by fluid aspiration. Should an empyema develop it is apt to be small,

A striking demonstration of the value of penicillin and recovery rapid. is shown in the heavily contaminated cases in which lung ussue has been divided in the open pleura. Finally, the patient's postoperative course with pencillin, is smoother there is earlier rising and a shorter hospital stay In a larger series of cases the mortality should be consistently lower since the dangers of putrid empyema and bronchial fistula are decreased with the use of penicillin ROBERT R. BIOTLOW M.D.

Adams, W.E. Thornton T.F. Jr. and Cariton L.M. Jr. The Use of Blood Plasma for Filling the Pleural Space following Total Pneumonec tomy Ann. Surg 1945 122 905

In view of the results of experiments on a variety of animals Adams and his associates found it worth while to test the influence of filling the pleural space with plasma following total pneumonectomy in man. Eighteen patients received such treatment and 10 additional patients used as controls, received no plasma. The usual method of management consisted in the determination of the red cell count, hemoglobin value and plasma protein prior to opera tion. At the time of surgery between 500 c.c. and 600 c.c. of plasma were introduced into the pleural cavity at the closure of the thoracic wall and 200,000 units of pencillin were placed in the pleural space of

Between 1 and 3 days after operation, following o of the 18 patients. chest fluoroscopy the remainder of the residual air was removed and replaced with plasma usually amounting to from 200 to 400 cubic centimeters. From the data presented and also from studies as

yet unpublished, it was evident that the greatest drop in red cell count, hemoglobin and hematocrit readings occurred between the third and fifth day after surgery Following this there was a slow return to normal but in most instances the preopera tive plasma protein level had not been reached by the end of the 2 weeks following operation

The lowering of blood plasma proteins was also reatest usually by the third to the fifth day but the fall dad not always parallel that of the hemoglobin In some patients the red cell count and hemoglobin remained at very nearly the preoperative level al though the plasma proteins fell. When the proteins were lowered to from I to 15 gm per cent they usually had not returned to the preoperative level by the end of a weeks following operation.

The average fall for 14 patients who received plasma in the pleural space was 0 00 gm per cent In contrast to this, the average fall for the control group was 1.48 gm per cent or almost twice that of the treated patients. It was seen moreover that a high percentage of the treated patients had only a slight lowering of the plasma proteins and main tained a higher postoperative level than the controls

The incidence of serious complications and the mortality rate were almost twice as great in the control group as in the group which received plasma in the plaural space following resection of the lung.

It is thought that although the series of patients is not large, the discrepancy between the two groups is significant.

A striking difference in the incidence of postoperative empyems and bronchial Sixula was seen
between the methods of bronchial closures. Of the
1s patients in whom as row suture technique was
employed 4 developed an empyems, 3 of whom had
a bronchial pleural fixula. In contrast with this,
none of the 16 patients whose bronchial stump was
closed by a single row suture technique developed
either an empyema or fixtula following operation.

Delmas, J. E.: The Operative Treatment of Fistulous Empjemas following Presumothoras: (Traisminate operatoric de los emplemas fatulizados postneumotocicios) Res espan. cir braunal study 945 5 170.

The author discusses the operative treatment of cutaneous fistules complicating a spontaneous or therapeutic pneumothorax. He performed 7 thor accetomies on account of chronic empyema following pneumothorax. These cases did not include empyems following pleurisy or traumas of the chest. His material belongs to Hedblom's groups 2 and 4. Usually in such cases an encapsulated pleural cavity is found with the mediastinum and the corresponding lung retracted the pleura has lost its ability to expand, the ribs are practically in contact with one another and there is a corresponding deformity of the chest. Multiple listules with surrounding cutaneous ulcerations are present. As a rule the condition is complicated by myocardual degenera tion and visceral amyloidoula.

As to the treatment, extrapleural thorscoplasty cannot always be carried out. To replace thoracec tomy Kirschner suggested intrapleural methods after an anterior resection of the second and third ribs. In selected cases pleurectomy may be per formed.

Schede a extensive thoracectomy is a very scrious intervention which should be performed in stages. Mosaldi suggested a combination of intrapleural and entrapleural methods. Sanchruch performs a para vertebral columnar thoracoplasty on the first to the much ribs in the first stage, in the second stage he removes completely the tenth and eleventh ribs and obliterates the empyems and in the third stage he performs a parasternal resection of the first to the eighth ribs.

The author modified Braun a procedure, which in turn is an improvement of the original Schede method. It is advisable to make the intervals between the various stages of the operation as abort as possible to prevent degeneration of the thoracle wall. As a rule in the first stage is upperfor paravertebral resection of from 3 to 7 ribs is performed. In the second stage a paravertebral columnar merrics of the lower ribs is done and the intercostal space are resected. In the third stage the picurectory is dec-Sometimes the first stage consists only of an extenresection of the first to third ribs with corresponding cartilages in the second stage a paravertend a section of the first to fifth ribs is performed and the intercostal spaces are resected in the third starparavertebral resection of the sixth to the elevent rib is performed and the fourth stage consts of pleurectomy Great care is taken to have the drainage tube in place during the interreston by cause the alteration of the thoracic wall after a resections makes the introduction of a draining the into the old fistula very difficult. The intercencan be done under local anesthesia supplemented by a costopleural bloc.

a costopleural bloc.

The author concludes from his studies that installed the fathloss empyrems without retentes of per a patient in a good general condition can be trustely drainage and aspiration. A residual carly repara limited plaunectomy A frigit carly with considerable pachyplaunita should be treated pleurectomy according to the described technique Pleurectomy about he preceded by an intermediate of the intercental nerves. If the centry is much one stage limited pleurectomy should be performed to the intercental nerves. If the centry is much one stage limited pleurectomy should be performed.

tive but not in dry pericarditis. JOSEPH K. NABAT M.D.

Ivanisserich, O and Martiarens, L. H : Treatment of the Engaged Heart. Chronic Constrictive or the Editation destroyment consciences remeanurs (transmento de construi spraousco La pericardita crónica constrictiva) Bol Issi

clis. quie B Air., 1945 21 239. The authors operated on 8 patients with chronic constrictive perfearditis. Three patients were cured I patient showed marked improvement in his condi tion, 2 patients showed temporary improvement but death occurred later on and 2 patients succumbed

An intervention should not be undertaken until the primary condition has passed its acute stage to the operation. This statement holds true particularly in cases of tuberculosis of the percardium. Surgical inter vention undertaken to free the heart during the evolutionary stage of tuberculous has proved un evolutionary scage on tubercurant as a part of successful and caused death. The patient developed a bacillary meningitis and died from it. Tuberculous leavons were found in the extirpated pericardium Patients with a marked passive cardiac deficiency

should not be subjected to an operation.

Before the operation an attempt should be made to improve the patient a condition and the cardiac efficiency Furthermore, serous effusions should be evacuated to prevent if possible a new formation of adhesions.

Blood transituous should be given before the operation if necessary Either local or general anesthesis, with cyclopropane or ether given through a trackest the can be used. Any approach with which the surgeon is familiar may be used. Extraptation of the pericardium should be as ample as possible. Total pencardictiony is not always possible on account of firm adhesions which are likely to crist in certain sones between the heart and the pericardium. In such cases which are relatively frequent a partial pericardictiony must be per formed. Experience has shown that many patients have fully recovered after partial extripation of the pericardium.

The authors obtained a cure in 37 per cent of their material. This figure compares favorably with that of other authors who show cures in from 22 to 30 6 per cent of their cases.

Shallard B.: Patent Ductus Arteriosus. Med J. Anstralia 945 2 353.

The prognosis in patients with patent ductus artenoms is poor apart from surgical treatment Shallard reports in detail the cases of 14 patients on whom operations were performed. Four succumbed to operation a from hemorrhage and 2 from other causes and 1 died from subsequent infective endocarditis.

In discussing the disgnoss it was thought that there is not one clinical sign which sione can be depended upon as being constant. The nummur described as continuous machinery water wheel, train in-tunnel may not always be found. In 2 of the patients the nummur at the initial examination was limited strictly to systole. The disatolic component developed during a period of observation of 6 months in one patient and during a period of 3 years in another.

X ray pictures are invaluable in diagnosis, but are not pathognomonic. Dilatation of the pulmonary artery was present in only two-thirds of the cases. Left ventricular hypertrophy was found radiologically and a devastion occurred in the electrocardiograms in 4 cases. Significant changes in the S-T intervals in two readings were observed.

Pallor a clinical sign not hitherto described, is considered important, and anginal pain on effort was reported by a adult patients. These symptoms are unusual in patent ductus arteriosus.

STEPHEN A. ZHOMAN M D

Paton C. N: Anothesia in Cases of Ligation of Patent Ductus Arteriorus. *Med. J. Australia* 945 2 362

Basal narcosis with avertin, followed by inhalation anesthesia with cyclopropane was found to be a satisfactory form of anesthesia in a series of cases of ligation of a patent ductus arteriosus.

Cyclopropane was selected because of its nontoxic and nonirritating features, the shallow type of respiration it produces, the case with which "controlled respiration can be instituted, the bit concentration of oxygen in which it is administed, and its reversibility. A standard McKenon in chine was used which is dillitated the application of accurately measured positive pressure.

Endotracheal intubation was an added strategy became a minimum of disturbance of cardae of respiratory function was experienced. Comba those either during or after operation were at prisingly few STEPREY & ZINGY MD

Edye, B. T : The Surgical Treatment of Paral Ductus Arteriosus. Hol. J Antolis, 195

Edye describes the procedure he employs a the surgical treatment of patent ductus arteroses. Se approaches the pathological conditions through a planned space, verified by skiagram to be opporte the second left intercostal area. An oblique poles over this intercostal space was made couring at wards and outwards in the direction of the fiber of the pectoralis major muscle from the margin of the sternum to the line of the anterior axillary ind. The muscle was spht and not divided. In the olde patients a curved incision was made with the covexity upwards to avoid the mammary tome. The pleural cavity was entered by increion of the intrcostal muscles and pleura, and the cartilages of the second and third ribs were divided. The istense mammary artery was sometimes divided between ligatures, but at other times the incision stopped short of it. If it was injured it caused troublesex hemorrhage and delay A rib spreader was inertiover gause sponges and the wound was with opened. A light gause pack was inserted to preter the collapsed lung. The diagnosis was confirmed by the characteristic thrill detected on painties at a near the sate of the ductus. Usually the anatonical structures including the phrenic and vages serve and the left subclevian artery were dearly visit. The ductus joins the nortic arch at or just beyond the level of the origin of the latter This preliment examination completed the mediastinal plean sa divided vertically between the 2 peres. The posterior less was raised to bring mto vice the recurrent nerve which hooks around the sorts in mediately to the left of the ductors, and is a not important guide to the latter The ductus will the located by making pressure over the interval be tween the aortic arch and the pulmonary artery at various points until the thrill was obstrated

The dissection of the ductus was a tedeor paress, fraught with considerate analytic brain was apt to be deficate and easily four. The interdibet ween the acritic arch and the policousty garm was gently widened by blant dissection with securred forceps a little distance to the cyli of ductus, and the process was repeated clear to the ductus until that aspect was freed. I smaller the acciden was carmed out on the opposite rate, it as recurrent larguegal nerve being used as a gable for forceps was then insignated posteriorly so as gast-

203

ally to open the interval between the ductus and the and the bronchus behind. It was during this stage of the dissection that the ductus was apt to be torn. The maneuver was assisted by counter pressure with the left index finger in the interval between the aortic arch and the pulmonary artery to the right of the ductus. Narrow malleable copper retractors were a

useful aid in the exposure of the ductus. The next step was the passage of a MacCormick dimector behind the ductus aided as before by counter pressure with the left index finger care had to be taken not to catch the posterior aspect of the fuctus with the instrument. When the dissector had seen passed no attempt was made as a rule to free been passed no attempt was made as a rule to free ductus any further posteriorly, but the distinct now loaded with number 8 silk, was passed and the ligature was drawn through. The ligature distinct the state of t slipped through with greater case when the dissector was in rile. A second ligature was passed. At or about this stage the ductus was compressed digitally and the effect on the circulation was noted. If after I or a minutes there were no untoward effects, the ligatures were carefully but firmly tied. By palpa tion and by auscultation with a sterilized stethoscope, it was determined that the thrill and murmur had drappeared The incision in the mediastinal pleura was sutured as well as possible. Any blood was aspirated from the pleural cavity and the chest wall was closed in layers. The divided costal carti lages sometimes were and sometimes were not mitted with catent. The ribs were drawn together with sharp hooks during the closure of the pleural cavity and the lung was encouraged to expand by he anesthetist and also by suction of air from the pleural cavity before hnal closure. No drainage was provided convalescence was usually uneventful, and only on occasion was it necessary to aspirate pleural fuld. The blood transfusion was continued slowly

It must be remembered that when cardiac ef throughout the operation. ficiency has been impaired it is possible the introduction of a large amount of blood may be detri-

### Gross, R. E.: Surgical Relief for Tracheal Obstruc tion from a vascular Ring. N England J M

In an infant with symptoms of tracheal obstruc tion (crowing inspiration dyspines intercostal and suprasternal respiratory retraction) there developed attacks of superimposed tracheitis, for which the patient was hospitalized on 4 different occasions Fluoroscopic studies made after the patient had a swallow of barlum showed what appeared to be a mass lying behind the caophagus, opposite the third and fourth thoract vertebra, with the esophagus itself pushed forward and narrowed in both the anteroposterior and lateral views. Instillation of liplodol showed a fairly marked narrowing of the traches just above its bifurcation at a level corresponding with the previously described esophageal This narrowing was apparent in the deformity

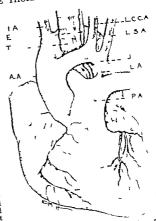

Fig 1 Arrangements of the great yearsels as found at operation. The ascending arts bifurcates into two branches one passes behind the exophagu and the other arches in front of the traches. The two branches join to form the descending torts. Within the vascular ring the coophagus and traches are compressed. AA-ascending commagns and dannes are compressed on satering and Lessophagus IA-immominate artery J-junction sorts companies of the two sortic arches LA-ligamentum arteriosum or the two acrus arenes in hypermentum arteriorum LCCA—left common earotid artery; LSA—left subclavian artery PA—pulmonary artery and T—traches.

anteroposterior view and was particularly noticeable in the lateral film

Operation was then performed at once, although the patient was in a precarious state at the time Under cyclopropane anesthesia the chest was opened through a left anterolateral incision and the pleural cavity was entered through the third interspace with separation of the third and fourth costal cartilages. The left pleural cavity was traversed to reach the mediastinal structures. When the mediastinal pleura was opened the aorta was seen to divide into two vessels which enclosed and greatly constricted the veneza when some and traches and then joined to form the descending norts. The left common carotid and left subclavian arteries came off the smaller anterior segment of the ring in the usual manner for the sortic arch and the much larger posterior segment gave

First the ligamentum arteriosum was divided beissue to the innominate artery tween silk ligatures to allow the pulmonary artery to fall forward and away from the traches this procedure did not have a marked beneficial effect on the

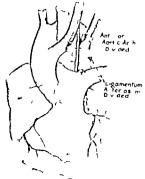

Fig. Surgical procedure. The ligamentum arteriorum was di ided to llow the pulmonary artery i displace forward. The aterior arch of the sorta was di ided t relieve compression of the traches.

respiratory exchange and the anterior segment of the ring was then divided between the two branches

he soon as the anterior acrtic such had been di yided the respirations quieted down most of the crowing disappeared and the respiratory shift in the mediastinum diminished to a normal degree. The chest wall was closed in an appropriate manner the left lung being compl tely expanded before final repair of the wound and the patient was placed in a steam room and given sulfadizzine and penicillin

After 1 week the patient was alert and playful and had no distress of any kind. When the car was held close to the chest a faint inspiratory sound could be beard during and immediately following degintition of food these inspiratory sounds became slightly louder apparently because the esophagus was still displaced forward by the sortic arch behind it and was causing some pressure on the posterior

Roentgenographic examinations 1 month later showed no change in the esophagus, and the traches still presented some narrowing above its bifurcation but this was distinctly less marked. Although its left border had straightened out considerably there was some indentation along its right side perhaps due to some residual pressure from the left common carotid artery which was now passing across the traches from in front, or due to incomplete development of the trachesi ring following the longitudes

a scular rines of this nature do not always the rise to important clinical symptoms but sing the compression of the traches is areat enough to rive tree to respiratory distress, surgical division of surportion of the ring should offer an excellent dans for relief of the symptoms.

### ESOPHAGUS AND MEDIASTINIA

Lam C. R.: Surgical Treatment of Coopulat Atreda of the Esophagus. J. Palia. 5 Iai,

Until Leven in 1010 reported that a child had survived the serious preliminary operation of a multiple stare procedure for conrental stres of the esophagus, and that if an antethoracic skin tale could be constructed the case could be called in ces ful the outlook for the child born with a obstructive defect in the esopharus was hopden

The indirect method, however had may deadvantages and it soon gave way to the openton

of direct anastomovis.

L'ophareal atrenas may be classifed as folion type 1 in which there is complete absence of the esophagus (rare) type r in which there is an upper and a lower segment ending in blind nonche (ale rare) type 3 in which one or both of the segment communicate with the traches or bronchus. Type; is subdivided into type 1s, in which the fatels s between the upper segment and the tracket, type 3b, in which the natula is between the lower segment and the traches and type 3c, in which bets arments communicate. Type 3b is encountered non frequently than all other types combined and at counts for from 80 to 00 per cent of all congestion atresias of the esophagus.

If a newborn infant has a tendency to choke on as own mucus or is unable to take feedings, marthe roentgen studies should be carried out and if a cagenital lesion is present, its type can be determed

with considerable certainty

For a successful operation, three objectives are order (1) provision must be made for feeding the infant (2) regurgitation from the stomach through the lower segment into the traches and brocks tree must be prevented (1) the blind poets of the upper segment must be opened to allow the escape of swallowed salva. These requirements would be set by gastrostomy ligation of the lower cooksen segment and marsuplalization of the apper posch With these three procedures completed, the star tion would be compatible with life, but permanent gastrostomy feedings would be necessary unless at antethoracic esophagus could be constructed (o the other hand, the operation of direct anatoms meets at once all the essentials for the establishment of normal functional and anatomic conditions.

Most or all of the operation is performed union local anesthesia. A transfesion of approximately 75

c.c. of blood is given through a cannula inserted in an ankle vein. Access to the posterior mediastinum is gained by exposure of the vertebral ends of the second through the sixth ribs, subperiosteal resec tion of short lengths of these ribs section of the third fourth and fifth intercostal bundles, and areful reflection of the parietal pleura from the ertebral column. It is necessary to ligate the trygos vein on the right or the upper two or three intercostal arteries on the left, to open up the space behind the traches where search will be made for the datal segment. The upper segment is identified by the palpation of a catheter which has been introduced through the mouth The lower segment is then located and ligated as close to the trachen as possible It is cut transversely distal to the ligature and a corresponding opening is made in the blind upper segment. End to-end anastomosis is per formed over a catheter and with the use of fine silk in dural or eye needles. If no distal segment can be found or if after ligation the segment is too short to be connected with the upper one, resort to an in

Immediate postoperative care consists in an direct method is made oxygen tent incubator, extreme vigilance in the aspiration of secretions from the pharynx and noth ing by mouth for 5 days parenteral fluids being administered by hypodermoclysis On the fifth day if inspection of the dressing shows no leakage of mucus from the wound cautious feeding by mouth is begun. One-half ounce of 5 per cent dextrose solution is offered every two hours. If there is no regurgitation or evidence that the anastomosis is not intact this amount is gradually increased to a ounces. On the seventh postoperstive day I onnce of formula is given every a hours. If this is toler ated all restrictions on the feeding of formula are removed after the tenth day Vomiting should be avoided for it would undoubtedly put strain on the

Scott W J M : Idiopathic Dilatation of the anastomosis Esophagus, Ann Surg 945 122 582

Today it is recognized that dilatation of the sophagus without obvious pathological cause is a numon condition. In fact it is approximately one hird as frequent as carcinoma of the esophagus, being second only to the latter in the statistics of the hrger clinics (MacMillan) It appeared earlier in the literature under the purely descriptive term, ectasts or idopathic dilatation of the esophagus. But today the author's etiological conception is usually introduced into the name, and the condition is most commonly designated as achalasia of the cardla or cardiospasm although there are still widely conflicting opinions about the cause of the dilatation

Fortunately for the patients who suffer from this serious and usually progressive difficulty in the passage of food from the dilated esophagus into the stomach, treatment does not need to wait for a final determination of the cause by dilatation of the

cardia, either on one or repeated occasions, the symptoms in the majority of cases are adequately con trolled However some of these patients do not respond satisfactorily to this and the other conserva tive measures of treatment. Although the percentage of this refractory group is small, the failure to re spond to conservative measures offers a serious problem for two reasons first, because of the complete failure of the usual therapeutic measures to alleviate the condition and, second because of the progres-These cases sive seriousness of the symptoms constitute a small but important group and their relief has become a challenge to the general surgeon

as well as to the esophagoscopust Dilatation of the csophagus without any clinically discoverable obstruction is not a disease entity but a syndrome. At least four clinical types can be recognized each with a different ethology namely (1) achalasia of the esophagus, (2) true cardiospasm (3) partial constriction near the cardia, and (4)

Achalasia is probably the most common type. It dolichoesophagus usually responds well to dilatation. In true cardiospasm the reflex originating focus should be discovered and removed Those cases caused by a

partial constricting band near the cardia are few in number but are probably resistant to conservative treatment. Dolichoesophagus, an S-shaped length ening with pooling of esophageal contents at differ ent levels, should probably be operated upon difficult to control when the dilatation becomes ggantic and a complicated by infection of the

Subdiaphragmatic esophagogastrostomy of the esophageal wall. Finney pyloroplasty type appears to be the opera tion of choice in the cases of idiopathic dilatation of the esophagus that are resistant to the usual con servative measures. The symptomatic results of this operation are usually excellent whether or not the dilatation of the coophagus is entirely corrected The danger of the operation is not excessive when proper precautions are taken. After this operation has been employed more extensively the number of cases in which it is indicated will probably be con sidered as having increased but it should never replace conservative dilatation in the majority of CASCS.

Olsen A M O'Leary P A, and Kirklin B R.; Esophageal Lesions Associated with Acroscleroand Scieroderma. Arch. Int. 11 1945, 76

Approximately 10 per cent of the patients suffer ing from acrosclerosis or scleroderma made complaints referable to the esophagus. The most common complaint was dysphagia. there was also substernal burning after meals, especially when the patient was lying down

Positive roentgenographic or endoscopic findings were demonstrated in 18 cases. Dilatation of the csophagus similar to that seen in cardiospasm was observed in 7 cases and hiatal hernia with intra thoracic stomach was demonstrated in 9 cases. In 2 other cases scierodermic changes were demonstrated in the esophageal wall.

Acrosclerois should be distinguished from other forms of scleroderma. In acrosclerois the phenomena of Raynaud's disease are present prior to the demastological changes or coincident with them Thirty three of the 35 patients who had esophageal symptoms presented the clinical syndrome of acrosclerois. All of the 18 patients who had positive roentgenographic or endoscopic findings had acrosclerois.

The basic alteration in acrosclerosis and scleroderma is sclerosis of the connective tissues of the body Sclerodermic changes in the connective tissues of the esophagus are chiefly responsible for the esophageal disturbances. It should be emphasized that esophageal disturbances are extremely uncommon in Raynaud a disease per se Reduced or absent muscular activity in the wall of the esophagus and shortening of the exophagus apparently result from sclerodermic involvement. Disturbances of the autonomic nervous system may play some part in the causation Clinical diagnoses of cardiospasm and hiatal herms of the short esophagus type are made most frequently in these cases. Stenosis of the lower part of the esophagus and the esophagugastric junction may occur with histal hernia as the result of chronic inflammation of the lower part of the esopha gus. This inflammation is the result of incompetence of the cardiac sphincter with regurgitation of the mastric secretions.

The treatment of the esophageal lesions of acroscleroils consists of the passage of sounds over a previously swillowed thread Fairly satisfactory results have been obtained. The esophageal stenosis of 1 of these patients was treated satisfactorily over a 10 year period by repeated dilutations.

### Clark, D. E. and Adams, W. E.: Transthoracic Esophagogastrostomy for Benign Strictures of the Lower Esophagus Ann. Surg 1945 2 942

Clark and Adams report in detail 5 cases of trans thoracic exophagogastrations for beingn attricture of the lower exophagus. None of the 5 patients was considered to have cardionasm. In 1 case the stricture followed the ingestion of lye, in another it was associated with generalized scienoderms, and in 3 cases there was no ethological factor that could be ascertained. In all of the cases however the obstruction either started above the disphragm, or the entire lesion was in the thorax, so that transabdominal cardioplasty was out of the question.

Four of the patients had repeated dilatations with only temporary relief and z of these required guatrostomies when dilatations became impossible. The fifth patient because a malagnancy of the cardia was anspected was not subjected to dilatation.

Employing positive pressure ethylene-oxygenether anesthesia the authors opened the chest through the eighth rib bed in 4 cases, and through the eighth interrpace in r case. After proper a tractions of the long and extralor of the power nerve, the displangum was included from the power toward the esophagent hatrus. The piece use moved to facilitate mobilization of the storest celthe fundas was brought up late the therat was earth of the sorts. The anastronesis yet was the just above or at the upper level of the tritings and just above or at the upper level of the tritings and side to side anastromosis was made. The displangwas closed about the stomach and snirred is a wall. The wound was closed thirty

All of the patients made an unevential reason and are still alive and enjoying a normal cristor. It is concluded from these selected cases of he

If a perforation occurs in the crevical portion of the exophagus pain develops at the base of the neck the stopping pain develops at the base of the neck the perforation involves the thoracie portion of the scophagus the pain is confined chiefly to the region between the acapulae, and the respiratory move the perforable perforation occurs in the distances pain. If the perforation occurs in the distance pain if the perforation occurs in the distance pain in the perforation occurs in the distance pain in the presence of the second painting the presence of an acoustic bacteria in the sputum and lever are other important signs

The author treated an 18 year old girl who de veloped dysphagia following the ingestion of 10 c.c. of nitric acid. Two months later roentgenograms showed a cicatricual atenoals of the esophagus of caustic origin. The entire esophagus was rigid and stenosed On esophagoscopic examination a stenosis was encountered at the upper aperture, and sounds, from size 12 to 18 were introduced through Jack son a tube. The patient's condition improved but she returned 9 months later with intensive dysphagus Sounds from size 12 to 14 would pass only the upper portion of the esophagus and roent genographic studies confirmed the diagnosis of a high stricture. Dilatations of the esophagus were continued for 11 days Two weeks later the patient returned with a more intensive dysphagia and edema and pains in the left side of her chest. The pains were radiating toward the left upper extremity and the left side of the spine. Gastrostomy was planned in order to facilitate alimentation. X ray studies revealed a homogeneous, sharply circum scribed shadow in the upper mediastinum especially on the left side. The esophagus in that region had irregular outlines and a retention of barium was noticed 24 hours after its ingestion. The roentgenological diagnosis was mediastinal abscess of esopha geal origin with a suspicion of pulmonary abscess on the left side. Twenty thousand units of penicillin were given every 3 hours in addition to a blood transfusion. The temperature returned to a normal level after 48 hours and the pain disappeared com pletely after the administration of 1 000 000 units of peniciliin. Five days later x ray studies showed a complete disappearance of the mediastinal lesion it was believed that this lesion might also have been of

The second patient, 33 years of age had been complaining of epigastric pains and complete dysphagia for 4 years. The attacks used to come in the form of crues during which the patient was not able to swallow even his saliva. Gradually the attacks returned at shorter intervals so that at the time of admission hardly a day was passed without attacks Roentgenographic studies revealed a contraction of the crophagus at the junction with the cardia. An esophagoscope 7 by 45 could not pass the stenosis A dysfunction of the diaphragmatic histus with a resulting spastic condition of the csophagus was diagnosed and a mercury sound was passed. The procedure was repeated for 4 days. When the cophagoscopic examination was repeated a con tracture was encountered at the crkcopharyngeal level. The esophagoscope was withdrawn but in spite of careful technique the patient developed pain in the neck, especially on the left side frequent pulse, and a rise in temperature Roentgenographic examination disclosed a sharply circumscribed bomogeneous shadow in the upper mediastinum The clinical and roentgenological diagnoses were mediastinitis due to a perforation of the esophagus. Thirty thousand units of penicillin were given intra muscularly every 3 hours, in addition to a hypoder modysis of glucose in saline solution. The following day an edema developed in the left lower curvact region and the frequency of respirations rose to go per minute. The pain was redaring to the left side of the cheat and the left supraclavatular region. Only after 72 hours the fever panu, drypnes and other symptoms began to subside and it desappeared completely to days from the time the treatment had been instituted. The total amount of penicilliar given was 1,00,000 units. A gastrostomy was performed to facilitate the administration of food and retwormed dilatation.

The author atreases the point that in spite of a large experience of the esophagoscopht and extreme care, fissures of the esophagost wall may follow dilatation of the exophagost. A necrosis of the mu cosa gradually leads to the formation of a fistual with resulting mediastinitis. Blood transfusions and the administration of other fluids intravenously should supplement the administration of pencellin in such cases.

Forsee J II: The Use and Control of Thoracic Surgical Teams of an Auxiliary Surgical Group J Thorac Surg. 1945 14 425.

An auxiliary surgical group composed of a group headquarters, general surgical orthopedic, neurosurgical maxillefarial, thorace surgical, shock gas, and dental proathetic teams has been employed in the American Army for the first time during World War II

This organization under one central control group has produced a maximum level of competence and economy in the deployments of specialized surgical taient. Remarkable advances have been made in thoracic surgery since World War I and thoracic surgery since World War I and thoracic surgery since World war I may be supported to the first time in this war. The author a study is based on 13 months of experience caring for 2000 patients with thoracic luturies.

Thoracic surgical teams are composed of a thoracic surreon, an assistant surreon an anesthetist a surgical operating room nurse and 2 enlisted surgi-cal technicians. The chief surgeon should be a competent operator preferably with a sound basic training in general surgery, a good teacher and should have a thorough knowledge of surgical physiology of the thorax. The assistant surreon should have a minimum of a years of survical train ing with some experience in the medical aspects of thoracic diseases. The anesthetist should be expert in endotracheal and positive pressure anesthesia in bronchoscopic aspiration of secretions the management of shock, and in the recognition and treatment of disturbed cardiorespiratory physiology nurse should be an able instructor in operating room technique able to teach the principles of asepsis to soldiers without previous experience and have a knowledge of the technical features of the specialty All team members should be sincere, have physical stamina, and the ability to adapt themselves to varied and changing situations.

The teams work in many different hospital are supplement the regular staffs when the requirement for survery exceed the canacity of the tender of

The equipment is minimal and consist of the army basic instrument set, and a supplement thoracic set including a bronchoscope and sunsories. An electric suction apparatus and purish anesthesia equipment complete the list.

The thoracie surgical teams are employed is a war for the thoracie surgical teams are employed in the woulder those who cannot be transported here woulded those who cannot be transported here to the real field supplied to the real field of the surficial cleans of an antiffure surgical case.

the surgical terms of an auxiliary surgicity surgicity. It is here that surgical care can be first assisted. These bospitals are located in the rear of striken area and in dose conjunction with a Grassic clearing station. The platoon of a field sopiule capable of moving on short outer as they from one another. The platoon, or part of k, bit behind and becomes a holding end. When after patients have been extracted, in from a to so we the unit is available to kep frog another place and become the forward hospital.

An active platoon requires 1 general seried, thorace, and 1 shock team. The thorace said team not only operates but also shrine in but an agement of thorace wounds and teacher broad scopy to aneithetists and surgross. The thorace surgross a interest in interestal nerve block per diversity to be a surgross and the surgross and the surgross and the surgross and the surgroy catheter application of trackers child secretions, the management of istalisated foreign bodies, and traumatic hemothesis the set assimulas to all surgross treating severe thank records.

Certain types of cases which were considered for priority surgical problems, in the fight of entitherapeuthe measures perclosely enasoried is requestly transportable, and inmediate reports no longer considered necessary one tonger surgical team, however during a period of year, operated on 92 intrathoracic conditions, of with operated on 92 intrathoracic conditions, of with were combined thoraccolodomial womas, to thoracotomies and 56 were penetrated or forating injuries. At the same time this proforating injuries. At the same time this proportated on 44 palents with abdominal womas.

First priority surgical cases represent only for cent of the total cases arriving at the draw, the station. The majority are to tensated to the evacuation hospital a few mines ponely begins about 25 per cent, and anything less small cates an improper selection of cases.

The overall mortality rate in 346 intra-abdorbal wounds (20 per cent of which were combined the acoshdominal wounds) treated by surgeons of this group was 30.6 per cent. Pulmonary complications caused 27 per cent of the deaths, while peritornize was responsible for only 11.4 per cent. Another series of 256 intrathorated wounds with 43 per cent thoracoshdominal injuries showed an overall mortal try of 28 per cent.

These figures indicate that most patients were wounded with high explosive shells, and that the highest percentage had multiple major wounds. Thoracic surgical teams working at this level must be connected to do major abdomlinal surgery.

The surgical teams of an auxiliary surgical group have done much to develop the phase of forward surgery. They have exerted a remarkably favorable influence on the morale of combat troops and have eliminated the temptation for clearing and collect ing companies to indulge in herore surgical procedures which they were never designed or equipped

to carry out.

The evacuation hospituls, located from 3 to 15 miles to the rear of a first priority surgical hospital, treat oper cent of the casualties from the divisional classification of the casualties from the divisional classification. The percentage of abdominal and combined thoraccabdominal injuries treated here. An appreciable segregation of cases into the surgical specialties is practical. In such 400 or 750 bed installations, thoracci surgical teams have been useful to supplement the regular thoracie surgeal section or furnish qualified person held for qualified thoracies surgeon is on the regular staff. It is highly desirable to have 2 thoracie surge at teams functioning in an evacuation hospital and devoting their attention to the treatment of patients with major thoracie intures.

In quiet periods at the front when there is no need for beds for imminent battle casualties, certain surgical procedures such as the removal of intra pulmonary foreign bodies and pulmonary decorties ton for oreanizing hemothorax are undertaken.

In fixed installations station or general hospitals in the base section area, the thoracic surgeons have a real opportunity. Every effort is made to return the patients to duty within oo days. This policy has led to several noteworthy contributions the removal of intrapulmonary foreign bodies within 10 days to 3 weeks after injury the radical management of massive organizing hemotherax by thoracotomy evacuation of the clot, and decortication of the lung The same procedure applied to established post tranmatic empyema with penicillin therapy as an adjunct has led to immediate healing with a fully expanded lung. This has been one of the significant advances in the surgery of World War IL. To the thoracic surgical teams of an auxiliary surgical group goes much of the credit for these advances The use of thoracic surgical teams in fixed in

stallations often has permitted the completion of the reparative phase of surgery by the same surgeons that have dealt with the initial phases of wound

management in the forward hospitals.

The organization of a large number of highly trained surgeons into aurical teams under one central control was new and untried several years ago Few hospitals considered the need for the assistance furnished by such teams. However, today the usefulness of such an organization is fully recognized and appreciated by all who have first hand experience in the problems confronting the medical science of an active theater of operations.

### SURGERY OF THE ARDOMEN

#### ARDOMINAL WALL AND DEDITOREUM

Brandon, W J M: Inguinal Hernia; The New Muscular Internal Ring Lener Load. 945 240 8 2

The author points out that the only common factor in the various types of hernia repair is the retention of the original muscular internal ring. Closure of this ring when the cord and testicle are removed has proved uniformly successful. The conclusion is drawn that the internal run is the potential source.

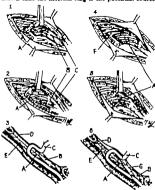

Fig. 1 A, Incision of internal oblique and transversalis muscles B conjoined tendon C, spermatic cord.

Fig. 2 A, Incised muscles reconstituted to form new

source of conjoined tendon to Poupart ligament.

Fig. 3. A, Portions of Internal oblique and transversalis nuncies satured medial to cord B satured confolored tendon D transversalis fascia E, lateral portion of internal oblique and transversalis muscles.

Fig 4. A, Internal oblique and transversalis muscles incised F muscles separated in the line of their fibres. (Spermatic cord omitted.)

Fig. 5. New muscular internal ring full constructed. Fig. 6. A. B. (astured cooledned tendon). Anterior blade of shutter giving full protection to true internal ring: C. spormatic cord enserging from new muscular internal ring after taking an S-shaped bord. D. transversalls facula forming posterior blad of shutter and protecting new full results of the shutter of

of weakness and that all recurrent hernias may be shown to involve the internal ring

A modification of the Rassini renair is described in which the essential feature is the construction of a new muscular ring. The internal oblique and transversus abdominis muscles are incised so as to form a V" at the old internal ring This muscle is then sutured about the cord to form a new ring as shown in Figs 1 2 and 4 A slightly different technique in which the fibers of the muscles are sollt at the anex of the "V" to further move the internal rine from its original position, is shown in Figs. 4 c and 6 In this way the obliquity of the emergence of the spermatic cord from the abdomen is changed and made more angular. There is then a two bladed "shotter" over the internal ring-one the transversalis fascia, another formed by the new mucular ring, and both permanently closed and not in opposition to one snother

The author concludes that for the moment this new suggestion in the repair of inguinal herns is a thesis and that proof of its efficacy must await the test of time.

#### GARTROINTESTINAL TRACT

Cancino, A. The Arterial Circulation of the Stemach. Gastric Hemorrhage (Circulación arterial del estómago. Hemorragia pistrica) Res Gatresides ous 10 ot

The author removed the stomach and the adjoining part of the decoleram from calavers, preserving all the attricts. Specimens were obtained from fresh cadavers to avoid maceration of the tissue. The main arteries were injected with a radiopage substance and roentgenograms were taken. In this manner the author studied the distribution of the blood vessels in normal stomachs and in those with peptic ulexar.

he came to the conclusion that there is a perfect equilibrium between the arterial pressures of the main arteria. Various factors collaborate in the regulation of the pressure velocity, and quantity of the blood passing each branch. One coal expect that a peristalite contraction might produce as anomic zone because of the compression of the blood versels, but in reality this is not the case. The diretion of the main arteries is identical with that of the peristalite waves, which facilitates the blood flow Numerous anastomises also contribute to the maintenance of a continuous blood current.

The diagnosis of the origin and mechanism of a grave gastroduodenal hemorrhage is of paramoent importance in the selection of proper treatment, namely the choice between a pure expectant treat ment, active medical therapy and surgical intentition. The gravity of anemis must be determined by a study of the blood pressure pube blood count, and the amount of hemoglobin The determinations of pulse and arterial pressure are of limited value be cause shock may produce a similar picture. Therefore the blood count and determination of the amount of hemoglobin are of greater value. A grave hemorrhage in the stage of evolution produces a pulse of gradually increasing frequency and an arterial pressure which gradually falls. On the other hand shock is followed by a fall of the blood pressure which remains stationary for a time, but gradually returns to normal levels in favorable cases.

A grave hemorrhage causes a progressive diminition of the number of red blood corpuscles. As a rule, an acute hemorrhage responsible for a fail of the number of erythrocytes to 3 000 000 within the first 3 hours gives a very grave prognosis. A red blood count of as little as I to 2 million is compatible with life, while in chronic anemias the organism may survive a count even lower than 1 000 000 crythro-

cytes

An amount of hemoglobin lower than 30 percent is not compatible with life and therefore a fall of hemoglobin to between 40 and 50 per cent requires a blood transfusion.

A pulse frequency between 130 and 150 gives a serious prognosis and a systolic pressure between 80

and oo is also alarming

While laboratory examinations furnish information as to the gravity of symptoms clinical examination should attempt to establish the cause of hemor rhages. It must be remembered that varnous conditions may be responsible for a gastroducdenal hemorrhage, e.g. ulcers hemophilia gastror varicustities, venous hypertension caused by a cirrhosis of the liver blood dyscrasias caused by choleli thissis primary or secondary gastric hemorrhage produced by Bantis disease syphilis of the stom ach, cancer and congestion within the stomach wall caused by retention due to pyloric steroois

Hemorrhages from capillaries or precapillaries are benign, as a rule, while those from larger blood

vessels require a surgical hemostasis

If conservative treatment is decided upon an schag should be placed in the dorsolumbar region, and not over the epigastrium because the vasoconstricting reflex of neurogenic origin can be atumulated casier in this manner. Liquids should be given hypodermically in preference to their intravenous administration in order to avoid an overloading of the circulatory system. The amount given depends on the quantity of lost blood the condition of the pulse, and the blood pressure. The amount of blood to translused also should be related to the amount of blood both.

In chronic anemia a relatively small amount of transfused blood may raise the blood pressure but this is not the case in patients with an acute hemor thage who tolerate large amounts of blood without a rise in their blood pressure. A few days may clapse before the blood pressure returns to normal limits after a transfusion of relatively large amounts of blood. A patient with 3 000 000 ery torrocter a collection of the coll

hemoglobin of 60 per cent, and a systolic pressure of 100 requires larger amounts than 400 c.c. of blood

Vitamin K should be administered intravenously in sufficient amounts. The oral administration of binuth is to be condemned because the drug has no local hemostatic effect and may provoke vomiting

No food whatsoever should be given during the acute hemorthage but after the bleeding has stopped spontaneously or under the influence of treatment, liquids and later on the white of an egg gelatin and chopped meat may be offered.

An internist should treat the patient with acute gastric hemorrhage until the etiology of the condition has been established. The cause of hemorrhage is the determining factor in the choice of definite

treatment.

The roentgenological studies of the gastric arteries convinced the author that an efficient hemostasis requires extirpation of the source of the hemorrhage JORPH K. NARAT M D

Dragatedt L. R.: Vagotomy for Gastroduodenal Ulcer Ann Surg 1945 122 973

In this communication the author reports the present status of section of both vagus nerves in the treatment of peptic ulcer The operation was under taken because of the conjecture arrived at by ex perimental work on the lower animals that pure gastric fuice as secreted by the fundus of the stom ach has the capacity to destroy and digest various living tissues including the wall of the jejunum, duodenum and even the atomach itself. The chief secretory abnormality in ulcer patients lies not in the production of a juice with higher than normal acidity nor even in the production of more normal juice in response to the usual stimuli, although there is some evidence that this occurs but rather in the secretion of abnormally large amounts of gastric juice in the intervals between meals particularly at night when the stomach is empty and there is no obvious stimulant

Through animal experimentation it was found that section of the vagus nerves to the atomach reduced the secretion of gastne fluce in dogs to one half or even one fourth of the normal level. The data obtained so far suggest that the hypersecretion of gastne juice in ulcer patients is neurogenic in origin and that, consequently a comparatively greater reduction should follow vagus section in man than in lower animals:

In all the author and his associates have operated upon 30 patients with peptic ulcer by sectioning the vagus nerves. The transthoracic approach by resection of the seventh or eighth rib is preferred to the abdominal approach although the latter has been used in 7 cases.

Postoperatively, the author employed the Insulintest to determine if all the vagus secretory fibers to the stomach were interrupted. The rationale of the test lies in the fact that hypogly cerna induced by an adequate dose of insulin stimulates the vagus secretor, fibers to the stomach probably by an effect on the central nervous system. No effect whatever occurs if the vagus section has been complete

Of the 30 patients subjected to the operation at the time of this report, I died. This patient de veloped postoperative bronchopneumonia. Thirty of the patients in this series had duodenal ulcers s had gastric ulcers and 7 had gastrojejunal ulcers. Eight of those with duodenal ulcer were subjected to gastroenterostomy in addition to the vagus section because of high grade pyloric stenosis. In most of the cases of this type the vagus section was done by the abdominal approach at the same time as the gastroenterostomy Only 1 of the patients with duodenal ulcer failed to obtain striking and persistent relled from his symptoms and in this case there were many features suggesting a neurous. The first group of patients have been followed up for 21/2 years and, so far have remained well on unrestricted diets and without medication. For the remainder of the pa tients a longer period of observation is required be fore conclusions can be drawn, especially in the cases of gastrojejunal ulcer

The operation has no effect on the secretory re sponse of the stomach to histamine or enfeiche but abolushes the stomalsting effect of insulin hypogly cemia and a sham meal. Vegotomy reduced gastric secretion in the empty stomach at night from 50 to 60 per cent. It also resulted in the reduction of hypertomotity but the tonus and motility of the stomach were not abolished. An interesting observation was the fact that patients who complained of consultyation before the operation were relieved of this disturbance. Further study of this effect is necessary. Haron Lernars M.D.

Riera M., and Diaz, F. Low or Infrabulbar Duodenal Stenosia (Estenosis duodenales bajas infrabulbares). Rev. med. Chila. 945, 73, 855.

In the majority of cases of duodenal stemous the narrowing is located in the bulb and caused by a peptic ulcer Reentgenograms show a pyloric stenous with a secondary dilatation of the stomach. Stemous in the lower segments of the duodenum is rare and may be due to vanous factors. As a rule, roentgenological studies allow a correct diagnosis and often throw light on the nature of the lesion.

An infrabulbar duodenal atenosis may be con genital or acquired and of intrinsic or extrinsic origin. A congenital atenosis is usually caused by a malformation. Complete duodenal atresia is in compatible with life. A ring of atrophic pancreatic tissue may cause a compression of the duodenum in such case a concentric stenosis of the second portion of the duodenum with smooth borders is seen in the roentgenograms. A diverticulum may produce a duodenal atenosis, especially when it is nilled with food. In this respect the condition may be compared with stenosis of the esophagus caused by a datended Zenker a diverticulum

A spastic condition must be taken into considers tion in an acquired duodenal stenosis. Such spasms may be caused by a stone impacted in the common duct. Roentgenograms are essential for the diagnosis in such cases. Tumors of the duodenal wall or an extrabulbar peptic ulcer may produce a stenoria of the duodenum. A cancer of the duodenum responsible for a stenosis has been reported. In the majority of cases an infrabulbar stenoris is due to an extrasic lesion. The second portion of the duodenum may be compressed by the middle collc artery if ptosh of the right portion of the colon changes the normal postion of the blood vessel. The root of the mesentery may compress the duodenum in patients with an intestinal ptosis or a short mesentery. In such cases the duodenum is compressed between the spinsl column and the mesentery. There is also an acute type of arteriomesenteric steposis the mechanism of which is still under discussion.

An extrinsic infrabulbar stemoss may be caused by a tumor in one of the adjoining organ, either by compression or infiltration of the doodnal val. Tumors of the gull bladder panners, server or the left kidney may cause a compression of the doodnal may be a compression of the doodnal may be a compression of the doodnal may be a compression of the doodnal with the compression of the doodnal with the compression of the woder of the compression of the woder of the compression of the comp

the organ, with compression of the deedeman. Hesenetric lymph glands enlarged on account of Hodgkin's disease, leucemia, or lymphosarcona may produce infrabulbar compression of the deademan. An aneutym of the aorts may also be responsible for such a compression. Pertinodenal adhesion, percobolecytitis, plastic postoperative peritodies, or congenital bands may cause a compression of the infrabulbar portion of the deadenum.

Roentgenographic studies reveal a dilatation of the duodenum above the stenosis and an abnormally long retention of the ingested barium. A vigorous palpation of the involved region may provoke antiperistaltic waves and in the presence of pyloric insufficiency a reflux into the stomach may be observed. An obliteration of the mucosal folds is typical for the distention above the stenoms. If the stenosis is not complete, irregular contours of the duodenum may be noticed in the roentgenograms. Introduction of an opeque substance through a duodenal sound may prove useful. Pendulous movements of the normal duodenum may be cofusing and therefore repeated examinations are desirable. A supernumerary duodenal loop in the second portion of the duodenum may also create confusing images.

The authors report 11 cases of infrabulhar deoder all stenosis, 5 in men and 6 in women. In 9 it was possible to establish a definite etiology while in 3 the cause remained doubtful. The ages of the mile patients ranged from 21 to 42 years and of the female from 40 to 78 years. Johnson X. Narat, M.D.

Houot, A., Fire Cases of Cholecystodnodenostomy (A propos de Cinq cas de cholécystodnodénostomis) Union med. Canada, 945, 75 24

As a rule, cholecystogastrostomy is preferred to cholecystoduodenostomy although it is a less physiological method. If technical difficulties are encountered occasionally a cholecystolelunostomy is per formed although it is the least satisfactory method

In the course of 10 years the author performed 3 cholecystoduodenostomies and only 2 cholecystogas-tostomies. Usually these operations are done on account of bile fistulas with great loss of bile or on account of retention incterus. The last mentioned indication was present in 4 patients in the author's material. All of them had a cancer with numerous metastases in close vicinity to the primary tumor and at distant places. In 2 patients jaundice was due to carcinoma of \(\frac{1}{2}\) atterns papilla in 1 patient it was due to a cancer of the pancreas and in a fourth it was due to a malignant tumor of the common duct

In 4 cases the anastomosis was employed as a palliative measure to limit bile drainage to suppress jaundice and to create in the patients the impression that they were cured. The patients survived the operation 14 months 3 months, and 134 months, respectively while the fourth patient succumbed to a bronchopneumonia on the eighth postoperative day

As a rule patients undergoing cholecystoduodienostomy are undermourished and icteric and suffer from pruritus which interferes with their sleep Small and frequent meals of easily digestil le food are prescribed. The preparation of the patient for the operation should not exceed from 8 to 20 days and therefore oral feedings are supplemented by the solution 500 c.c. in 24 hours, with the addition of from 10 to 30 units of insulin. The fact should be remembered that such individuals easily develop a hypoglycenic crisis.

In view of the fact that the majority of patients requiring this type of an operation are exchectle and have hypotension a daily injection of from 4 to 6 cc. of adrenal cortex extract divided in two doese, is given. The author avoids ephedrine on account of the resulting insomnia. However in the course of the operation an injection of 2 cc. of ephedrine with 5 cc. of adrenal cortex extract is given. From 6 to 10 cc. of this extract are administered daily for the first 3 days following the operation and lessor amounts are given thereafter until the patient is able to get out of bed

A hypnotic is given to provide sleep. As a rule the hypnotic is combined with to drops of a mixture of equal amounts of tincture of belladonna and tincture of cratacquis to intensity the action of the

barbiturates.

To diminush the hemorrhagic tendency of icteric patients, from 10 to 20 c.c. of a 10 per cent calcium chloride solution are given intravenously every day

for 4 days preceding the operation.

No food is given by mouth the first 48 hours following the operation and during that time 1 000 cc. of normal saline solution, from 30 to 40 cc. of a to per cent saline solution, and from 1 000 to 1 500 cc. of glucose solution with so to 40 units of insulin are given when necessary

Except in 1 case, the author employed local anesthesis combined with a basal anesthetic The

aneathetic given per rectum consisted of chloral, (a gm) potassium bromide (a gm.) 1 yolk of an egg and mlk q.s. ad. 200 c.c. for local aneathesis. The author used from 60 to 80 c.c. of a 1 per cent solution of novocaine without the addition of adrenalm be cause the latter produces a temporary hemostasis collowed toward the end of the intervention by a reflex vasodilistation and oozing. After the peritoneal cavity has been opened a mesocyzitoeduodenocolic aneathesis is obtained with a 0 5 per cent novocaine solution.

After the bile has been aspirated from the gall bladder the organ is united with the second portion of the duodenum Sometimes it is necessary to seps rate the gall bladder from the lower aspect of the lover Catgut No oo is used for the anastomosis. The rent is about 2 cm long. The incision in the duodenum is made in the vertical direction. The second row of sutures is made with linen or chromic catgut No. oo. Sometimes omenium is attached to the suture lime. Two drains are inserted one into the suture lime. Two drains are inserted one into the subhepatic region and the other at the site of the anastomosis. The drains are left in place from 2 to 48 hours.

JOHEP K. NARA M.D.

Spatolizano B : Atypical Initial Reticuloendothe iloma of the Jejunum Associated with Chronic Stenosing Jejunitis (Reticoloendoteiloma atipico iniziale del digimo associato a diginalte cronica stenosante) Gier ital. chir 1945 1 35

The author describes the combination of a chronic, nonspecific inflammatory process with a tumor formation of reticuloendothellomatous character in a 45 year old woman who was admitted with compaints of pain in the epigastrum of 1 year's duration. She womited on rare occasions Diarrhea alternated with constipation A considerable degree of malnutrition was present Roentgenographic studies disclosed duodenographs tenosis.

An operation was performed under a combined basal and local anesthesia. A deformity of jeunum 7 cm long was found 3 cm from Treitz ligament. In the involved region the intestinal wall was thickened and indurated and the corresponding mesentery was inditated and contained numerous small lymph nodes. There was a sharp line of demarcation between the affected portion and the adjoining healthy tissue. The lesion was resected and an end to-end anastomosis was performed. The patient recovered.

Reticuloendothelioms is characterized by (1) a mesenchymal supert and the capacity of producing reticular fibrillae (2) phagocytic activity (3) syncy tial structure, and (4) the tendency to develop thefuly in endothelial direction. The following varieties may be distinguished (1) tumors with a mesenchymal aspect, (3) tumors with a reticular aspect (3) tumors with a pulposplenic sapect (4) giant cell tumors, and (5) tumors with an endothelial aspect.

The inflammatory process in the author's case resembled regional lights. The author believes that

the tumor developed following the inflammatory process.

JOSEPH K. NARAT M D

Tan, C. C., and Liu X 1 Amebic Colliss with Special Reference to Perforation. A Study of 20 Autopaled Cases. Chin M J 1945 6 366.

During a period of 10 years the clinical diagnosis of amebic colitis was made in 349 patients in the hospital of the Pelping Union Medical College, In o of 20 cases in which autopsy was performed, per forations were found. Eleven of 20 patients gave no history of dysentery of those with perforation all except I were admitted with symptoms and signs of acute amebic dysentery which had been present from 1 week to 4 months. Of the entire series of cases more than half showed varying degrees of diffuse ulceration usually in the sigmoid colon and the cecum. The cecum presented the most severe lessons and the largest number of perforations. The ileum was involved in 7 of 20 and the appendix in 5 of 15 cases examined. The cecum was periorated in 5 instances, the descending colon in 4, the sigmoid in and the transverse colon in a instance. In a instances multiple perforations were found,

WALTER H. NADLER, M.D.

Pfeiffer D B. and Patterson F M S.: Congenital or Hereditary Polyposis of the Colon. 1 s. Surg 945 2 666.

In every individual who is found to have rectal polyps a complete study of the intestinal tract is necessary. This includes prototocopic examinations, barium enema studies (postevacuation films and double contrast studies), and, finally reentgenograms of the stomach and small intestine.

The family history of every individual with multiple polyposis of the colon should be thoroughly investigated since this condition is often on an hereditary basis. Early diagnosis and treatment is very important for intestinal polypis tend to become malignant.

A satisfactory plan of treatment includes fulguration of the polypa in the ansi rectum and sigmoid followed later by fleorectosigmoidostomy and finally, by colectomy. The outbook for these patients is good if treatment is begun early.

Five cases of multiple polyposis of the colon are reported 4 of which had a definitely hereditary aspect. The classification, etiology pathology symptoms, diagnosis and treatment of congenital

multiple polyposis are discussed and special emphasis is placed on the tendency of the polyps to undergo malignant changes.

JOHN E. KIREPATRICE, M.D.

Weinberger H A.: Observations on Large Bowel Perforations. Surgery 1945 18 547

In the Lenox Hill Hospital, New York, 19 cases of large bowel perforation were recorded among 1,100 and autopsies during the last 10 years. Ten of the 19 cases were attributable to a perioration complicating diverticulitis, 7 were due to malignancy and 8 were due to perforation by mechanical agents within the lumen. Four recent cases in which autopsies revailed perforations of the large bowel are reported in detail.

Attention is called to the high morbidity and high mortality in diverticulitis complicated by per foration. The prognosis is also grave in large bored malignances that are complicated by perforation, with may cause the first serious symptoms in from to to per cent of these cases.

Two unusual cases of perforation of the agmost due to an intraluminal insult are recorded one was due to impaction of a fowl bone and the other was caused by rupture after a vigorously administered

Treatment of perforation from any cause is essentially the same. The surgical measures stressed are early and generous draunage with a minimum of manipulation of the site of penetration and a proximal decompressive colostomy

WALTER H. \ADLES M.D.

Meyer K. A., and Kozoll D D.: Preparation for Surgery of Patients with Colon Lesions. Q Bull Verticest. Univ M School 1945, 9 249

By virtue of a carefully planned preoperative operative and postoperative regimen, it has been possible to resect the colon if unobstructed, perform a primary "open anastomosis return the colon to the peritoneum without performing a producal colostomy and close the wound without drainage with only one death among the first 26 nationts with lesions of the left half of the colon who were treated in this manner. This was possible only because of the many physiological aids with which the authors were able to surround their surgical patients. Th advantages of this procedure over previous ones in which a colostomy (either proximal to or at the site of resection) was required are (1) a more radical resection is possible because no bowel has to be spared for use as a proximal or distal loop of the colostomy (2) such complications of exteriorization operations as wound infection herniation prolapse fecal fatula, obstruction, and stricture formation are obviated (3) a temporary colostomy and the morbidity associated with its closure is avoided and (4) primary resection and anastomosis without proximal colortomy is a one stage operation with a shortened period of hospitalization and no return visits for subsequent operations

The authors describe their preoperative manage ment with special reference to diet parenteral ammo acids plasma infusions blood transfusions auccinylsulfathiazole vitamins enemas Levine tube suction complicating diseases and preanesthetic medication

The importance of an adequate dict in patients with malignant lesions of the colon is best illustrated by the incidence of hypoprotenemia in this disease the authors have reported an incidence of 30 per cent, compared to the average incidence of 23 per

cent in a large group of surgical lesions

The value of amino acid digests for parenteral protein nutrition in human beings both to supple ment that which can be given by mouth and to supplant oral feedings when the latter is unfeasible has been demonstrated. The availability of amino acids for intravenous use is an important adjuvant to surgery and can often be ideawing.

The use of plasma as a source of protein nutrition has long been recommended but subsequent experiences have indicated that it too has short-comings

If one remembers the constituents of blood one should not be surprised that whole citrated blood transfusions have proved the most important and in the preparation of patients for operation. The authors believe there is a striking effect produced by whole blood with amino acids and they combine these two fluids in clinical practice on the theory that amino acids will be utilized for tissue protein metabolism whereas the whole blood will be more effective upon the circulating proteins.

Succiny Invitable has been the single greatest boon to colon surgery and has given considerable confidence in the undertaking of primary colon resections by an open technique rather than to rely upon crushing clamps with which so-called asptic anastomoses are carried out. With the advent of this plan of chemotherapy not a single instance of postoperative peritonitis has been seen in the authors series of cases and only a patient de

veloped a wound infection which required drainage.

The indications for vitamin therapy in the preparation of surgical patients are manifold. Most of these patients have a deficiency of one or more

vitamins.

The first enema and cathartic are given prior to the start of succinylsulfathiazole therapy. The second enema is given during the 24 hour period preceding surgery this is done to allow the drug to attain as

high a concentration as possible.

Intragastric suction should be established before operation to prevent distention. Control of distention prevents tension on the suture line and is as effective as a proximal colostom; with regard to decompression. Also the intragastric tube will aspirate swallowed inhalant anesthetic gases if used and help prevent postoperative aspiration pneumonia. Still another value in the use of this tube is in the lact that the patient can drink freely immediately after operation which minimizes the dangers of a postoperative parotitis.

Because most patients with colonic diseases are in the sixth and seventh decades, a proportionately higher incidence of diabetes hypertrophied prostatic disease hypertension and oral sepsis is present. Unless the patient is acutely obstructed all of these conditions demand correction before bowel resection is undertaken.

The authors describe their operative management with special reference to anesthesia open versus closed resections, sutures, wound repair blood transfusions Levine tube suction and vasooon

strictive drugs.

Whenever possible they have employed nuper came spinal anesthesia which provided an adequate period of anesthesia without the use of inlying intraspinal needles.

Any attempt at following a so-called asoptic tech inque in anastomoris has been avoided deliberately, for it is believed that the use of clamps in closed resection is not without the danger of necrosis of the bowel edges and is cumbersome.

The authors employed the principle of fine inter rupted sutures on atraumatic needles in the anasto-

mosis and the wound as well.

Interrupted sutures are used in closing all layers of the wound

Blood transfusions are given during the operation although the patient may have received 2000 c.c. of more of blood during the preoperative period. This is the most effective means of preventing shock and compensating the patient for blood loss sustained as the result of surgery.

Suction with the Levine tube is continued during the operative period to decompress the stomach which might otherwise obscure the operative field to prevent the swallowing of inhalant gases if given, and to prevent the supiration of gastric content

through emesus.

Vasoconstrictive drugs are given to prevent the drop in blood pressure frequently seen with spinal anesthesia, the authors particular preference is

neosynephrin

Granted that the patient is operated upon most skillfully after having been prepared as carefully as outlined a successful result will not be achieved unless he is given equally paintaking postoperated care. This care includes a wide variety of therapeu tic adjuncts, many of which have been outlined in the preoperative regumen.

Attention must be paid to the physiological prin

ciples of fluid balance

Blood translusions were rarely necessary post operatively in patients who have been given 2 occ. or more of blood before and during operation However unlimited quantities of whole blood are administered to patients showing the need for it.

The rationale for the authors use of parenteral amino acids has been discussed but the need for them is frequently more acute because of starvation

which may follow colon surgery

The rationale for gastric suction has been outlined Suction should commence before the patient is sent to the operating room continued during the oper to the operating room continued during the oper ation and resumed immediately after his return to

Hyperventilation is employed routinely with mixtures of carbon dioxide and oxygen, and is ad ministered every z or a hours until the patient breathes deeply or coughs. By this means greater oxygenation of the pulmonary alveoli occurs, mucha is oxygenserion or the pulmonary asystom occurs, mucus in dislodged, and pulmonary complications are avoided oracogen and priminately compared to a real cutterer with a nasal catheter or nasel mask in patients whose condition is precar or nazzu mazz in patients whose complication.

us or who have a cartisal computation.
Vitamins are administered with the intravenous fluids in the dosages given during the preoperative period they are given orally when the patient re sumes a diet, but are usually not necessary when he

While the patient is on gastric suction, all sulfon where the patient is on gastric action, an autou amides are administered intravenously in desages and a second to maintain a level of from 8 to 13 mgm. per cent in the blood. Sodium sulfadiazine is the drug of choice and usually not more than 5 gm. per day is required.

The drinking of water is encouraged as soon as the natient returns to bed

Elevation of the foot of the bed is employed for the Energy and a che root of the pen is employed for the first 24 hours to prevent shock and encourage the drainage of mucus from the respiratory tract

Catheterization is required more frequently after spinal anesthesis and is done if the patient has not

Patients are placed in a wheel chair for 15 minutes on the first postoperative day and more frequently and for longer intervals thereafter They walk with-

The diet is not resumed until the Levine suction tube has been withdrawn.

Enemas are not administered until the fifth or sixth postoperative day and then only in small

All exteriorizations should be made through separate stab wounds and not through the upper or lower poles of an exploratory incision. Often it has been convenient to bring a colostomy out through a debrided wound of entrance or exit, but this is avoided if possible. There is a piace for tabe ce costomies in the management of single perforations of the creum. However in general, it is preferable to exteriorize such wounds The evacuation of the patient and the change of management that he h subjected to may result in periods of time during which the proper attention cannot be paid to the

I tube may be of advantage in diverting the atream of iteal contents in an ileocolostomy or it may be used in a colostomy but its period of usefulness is not very long as leakage soon occurs around

Questionably viable areas of colon due to a damaged mesentery or to trauma to the wall of the gut proper should be exteriorized

The management of war wounds of the color differs materially from the management of kniom of the colon generally encountered in civilian practice. The excellent results obtained in civilian practice by the performance of primary anastomosis on the properly prepared colon permits the immediate re placement of the anastomosed portion in the general peritoneal cavity. In dealing with emer gency war surgery it is believed that all colon in juries should be exteriorized and that no primary anastomosis is warranted.

Pierpont R. Z. Peterson F R and Dulin J W :
Operative Results of Surgery of the Colon for
Seoplastic Disease Surgery 1045 18 441

The operative results of colon surgery for neoplastic disease covering the period between January 1 1917 and December 31 1914 in the State University of Iowa Hospitals Jora City are reviewed and the results of treatment tabulated. Exploration was carried out in 221 patients and of these 171 had resection of the colon. a resectability rate of 52 percent.

Among the 224 patients operated upon there were 46 deaths a mortality of 20 per cent. Among 117 resections 23 deaths occurred a mortality rate of 106 per cent. Among 81 patients in whom a pal lature operation was done for the relief of obstruction there were 17 deaths a mortality rate of 100 per cent. Altogether there were encountered 124 lesions of the 12th side and 82 lesions of the 12th side and

The authors report that an increasing number of tesections with limmediate end to end anastomous are being performed in their clinic and point out that there is no one operative procedure which can be applied to all neoplasms of the colon.

WALTER H NEETE MD

Miles, W. E., Gordon Watson, C. Milligan, E. T. C. and Corbett, R. S. i. A Discussion on the Man agement of the Permanent Colostomy. Proc. A Soc. M. Lond., 1945, 35, 691.

Miles observed that very few doctors appreciate the value of the daily wash-out of the colon for con trolling bowel movements. There is no doubt what ever that bowel action can definitely be controlled by means of a daily wash-out with 114 pints of plain water at a temperature not exceeding 80 F as de termined by the thermometer. This is repeated if necessary Should the temperature exceed 80 F mertia of the muscular coat of the colon is produced which results in retention of part of the fluid used and several hours may elapse before the muscular inertia disappears. A plain wash out if properly administered can be relied upon to clear the colon completely of its fecal contents It sometimes happens that difficulty is experienced in introducing the tube into the colon to the required extent rule this is due to the attempt to introduce the tube when the patient is sitting up or standing or when he rauses his head in order to pass the tube under guidance of the eyes and puts his abdominal muscles on the stretch. In order to pass the tube the pa tient should be recumbent with the abdominal muscles completely relaxed One of the causes of difficulty in passing the tube is acute angulation of the colon at the point where it changes direction and passes forward to the opening in the anterior abdominal wall. Such angulation can be entirely prevented by mobilization of the terminal portion of the descending colon

A weak spot in the abdominal wall has been created by the passage through it of the loop of pelvic colon destined for the formation of the colos tomy In order to afford support to the weakened abdominal wall a well fitting coloatomy belt must be obtained. On no account should the patient allow himself to be persuaded to have a rubber bag at tached to the cup of the belt to act as a receptacle for feces. Such a bag creates suction and in the course of time the part of the colon which is proximal to the stoma. Is turned inside out and extruded through the stoma. It is important that the belt should be worn continuously when the patient is up and about.

The stome of a colosiomy should be prevented from becoming stenosed by systematic dilatation. For this purpose the patient must be taught to pass his index finger to its full extent through the stome as the coloriony wound has healed firmly the index finger to its full extent before flexing the distribution. As soon as the coloriony wound has healed firmly the index finger of the left hand (if the stome is on the left side) should be passed through the stome every day for a month then once a fortnight for two months and finally once a month for six months, when it will be found that the tendence to contract has ceased

(tokbox !! ATROX states that in order to secure a good working colostoms it must be well fashloned and first of all it is essential to secure a good snor by keening the bowel outside of the abdominal wall for at least three weeks by the use of a glass rod or other means it is also necessary to avoid undue tension on the mesentery. The stoma should be well clear of the anterior superior spine to avoid interference with the belt. The size of the opening in the abdominal wall should be just large enough to allow a inger to pass down on either side of the glass rod An ellipse of skin should be removed to prevent subsequent contraction which is apt to cause recession of the opening. All cups and bags should be avoided a plain celluloid disc is all that is needed nationts find this unnecessary and wear only a singlet

The colostomy is trained to act only when it is washed out, which is done at the same time each day with plain tepid water without soap and a flexible tube (size 14) which is passed up as far as possible with great care. The fluid is run in slowly preferably by Junnel.

When this is carefully carried out at the same inner each day the colon learns to respond in an automatic way and many victums carry on their work with little deability. In a small percentage of cases the colon will behave as if the stoma was the rectum and act regularly and automatically without a wash-out with or without a mild apperient. If there is a tendency to looseness disasters may occur

GABRIEL stated that after a colostomy (terminal loop left Illac, or transverse) has been established, we have to decide if the bowel is to be allowed to act naturally or whether the wash-out regime is to be adopted. He is opposed to the wash-out regime for colostomics for the following reasons

It is unnecessary because the great majority of colostomy patients have good intestinal function and with reasonable care and discretion in diet they achieve a satisfactory and regular rhythm with

formed colostomy actions

3 It is harmful because it is not natural for the colon to have a solution thrust fint of daily be it plain water normal saline solution or soan aware. Colonic lavage for prolonged periods induces a chronic entarth of the colon with a hyperenic nuccosa a contracted bowle lumen, and the excessive formation of mucus in other word this routine induces a state of catarrh and irritability in the colon which is exactly contrary to what is dear asked after a consensure.

3. It is dangerous because the passage of a tube up the colostomy may lead to perforation perionitis, and death. In hospital work a colostomy wash-out a rarely necessary in the immediate postoperative period and usually the insertion of a glycerine supperiod and usually the missrition of a glycerine sup-

pository serves the purpose equally well.

MILLIOAN says that there is no surgical substitute
for the rectum. The rectum is under the control of
the patient for storage and ejection. A coloatomy
can never be trained to have conscious sensations or
voluntary powers similar to the rectum. The crude
muscles of the abdominal wall cannot act like the
specialized rectal and anal muscles in retention and
expulsion.

The same rhythm or regularity of bowel action can be attained with a colostomy as with a normal rectum that is, the s4 hour rhythm for in all of us with or without a rectum this thind depends upon

the colon

This author states, We cannot control the colostomy but it can be controlled." He also maintains that Nature standard of one and only one motion a day can be reached with a colostomy. How then are we to attain but one bowel action a day for a colostomy?

The answer is by routine morning wash-out if the rhythm does not come naturally after a short trial. A bowel completely emptied by a wash-out followed by a morning bath and clean dressings enables a man to face the day and his fellows without handeau.

The bowel action is likely to be regular after the removal of the rectum if the daily evacuation before colostomy was by rhythm rather than by feeling.

CORBETT considers the subject under two headings (1) the part played by the patient and (2) the

part played by the surgeon.

The patient wants a regular evacuation of the bowel and freedom from the anxiety of leakage. He wishes to be able to carry on his daily life in much the same way as he was accustomed to do before operation. His part in the management can be carried out in one of two ways.

1 Training the bowel to act regularly of its own accord in order to have a daily action.

2 Washing out the bowel regularly every day. In the part played by the surgeon it is of greek importance that certain essentials should be remembered in the formation of the coloromy and in the management of the postoperative period. This will lead to easy management and avoid complex-

I There is a choice of three positions for the stoma at the left flium, at the rectus sheath and possibly at the epigastrium. Colortomies in all of these positions appear to work countly sell

2 The formation of an adequate sput is essential. A glass rod is popular easy to apply and very satisfactory. The rod or a substituted rubber tabe abould remain in position for a or a week.

for 3 or 4 weeks.

Butts, J. B., and Conley J. E.: Perinephric Abscess; Report of 3 Cases Simulating Acute Appendicitis. U. S. Aus. M. Bull. 1945 45 1051

In the differential diagnosis of any abdomal pain, one should coasider perinaphric abscers, although it is uncommon. The syndrome of obscure fever with pain in the right fants and should be to perinaphric abscers may be easily confused with accure appendicitist and lead to a deleterious appendectiony. The authors report y case simulating acute appendicits the confusion of the common processing the production of the property of the subscriptions of the production of the produc

A peringephre abscess is an infection outside of the kidney capsule with resultant necrosis of the perinal connective tissue and appuration in the real fossa. The cases presented were simple perinephre abscesses as contrasted to complicated abscesses as sociated with pathological kidney changes, Authorities differ in opinion as to whether all perinephric abscesses are secondary to some infection in the kidney.

Abdominal exploration may be undertaken when the clinical pacture of periophne absens simulate acute appendicatis, and when urinary abnormalities are absent as they were in these 3 case. Often there is a history of a sidn infection or a severe oper respuratory infection several days or even weeks be fore the onset of the first symptoms. In these 3 cases no such history was effected, although in case a severe back injury occurred prior to the onset of the symptoms.

the symptoms. Anorexia, fatigability and night sweats are early complaints, followed usually by chilis and ferring he fain in the right faink radiating to the costovertebral angle and to either of the upper or lover quadrants range be the earliest specific complaint. The 3 patients in this report all had pain in the right faink radiating to the right lower part of the abdomina Simeone reported that lesions involving the perinephrium anteriorly cause pain in the right lower abdominal quadrant. At theson reported that 1 of 117 patients with perinephric abscess presented with complaints of lower abdominal pain, and 8 of the 70 had associated abdominal rightly. Urinary symptoms are uncommon in case of simple perinephric sense of simple perinephric

abscess.

On physical examination the patients are acutely ill and may show evidence of weight loss if the discusse is prolonged. Most of them have tenderness in the right flank, and spasm and awelling are often present also. Sincone reported 2 of 34 cases with

tenderness present in the right lower quadrant only Scoliess with the concavity toward the affected aid due to paravertebral muscle spasm is a prominent sign of perinciphric abscess Secondary inflamma tory involvement of the process muscle may cause the patient to hold the hip flexed. Motion of the hip then causes severe pain

Positive x my signs such as obliteration of the posas shadow, enlargement of the kidney shadow concavity of the spine toward the side of the lesion decreased movement of the kidney and disphragm on respiration and displacement or distortion of the kidney or ureters may help to make the diagnosis Only 45 per cent of the cases show positive x may signs, so too much emphasis should not be placed on

negative findings.

In simple perinephric abscess the urne is normal unless there is some kidney abnormality. The presence of albumin and white blood cells in the urine indicates gross involvement of the kidney itself. The staphylococcus aureus is most commonly cultured from simple perinephric abscesses while in complicated perinephric abscesses while in complicated perinephric abscesses condary to renal calculus and infection the escherichia coli is found. Chemotherapy before operation may be responsible for negative cultures in some cases.

Prompt surgical drainage is the treatment of choice and leads to dramatic improvement in the symptoms. If the perinephric abscess is complicated a primary or secondary nephrectomy may be necessary. Usually the disease is far advanced when the disgnosis is made, 12 and 8 days respectively, intervened between the admission of the patient and operation in the reported cases.

There was no mortality in the reported cases of

sumple perinephric abscess while mortalities of from 14 to 50 per cent were encountered in cases of complicated perinephric abscess

ROBERT R. BIGGLOW M D

### LIVER, GALL BLADDER, PANCREAS, AND SPLEEN

Nigam, K. S., and Sircar J K.; An Additional Test Helping in the Diagnosis of Chronic Cholecystitis. Ind J Su g 1945 7 95

Patients with chronic cholecystitis show marked cholestero retention. The authors estimated the cholesterol in separated serum for which they used the colormetric method. In most of the cases the estimation was done on an empty stomach in order to eliminate the dietetic factor. The estimation was carried out on 86 cases.

The minimum figure was 73 mgm in a child aged to years and the maximum was 350 mgm. in an old man of 60 suffering from an enlarged prostate with secondary vestcal calculus therefore the average was 1450 mgm. The table shows the amounts of serum cholesterol within certain limits in the case In this sense of cases the reading is indper than that found in the whole blood in India by other worker but it approaches the readings in other countries

Serera Cholesterol	Note	ere Per	centag
Below 100 mgm	4		4 7
Between 100 and 119 mgm	13		7 4
Between 120 and 130 mgm	15	2	o i
Between 160 and 170 mgm	11	1	28
Between 180 and 100 mgm	10	1	16
Between 200 and 220 mgm	5		< 8
Above soo mgm	1		

The ingestion of food rich in cholesterol for some time has been known to produce an increase in the blood cholesterol. It has been the aim in the present work to study the changes in the amount of cholesterol in the blood of human beings after a single ingestion of fatty diet and to compare them with the changes so obtained in patients with cholecystitis At the very outset it may appear that the test of giving fatty diet may not be safe in cases of chole cystitis but fortunately in this series of cases no complications or trouble occurred. The diet which has been prescribed does not contain such an excess of fat that it upsets the patient, but it has enough cholesterol in it to make the estimation desirable The test need not be done in cases of acute chole evatitis in which the diagnosis is obvious certainly very helpful in the obscure and chronic cases. In scute cases the test should be applied after the acute symptoms have subsided and the patient is allowed solid diet

It was found that II of I2 cases showed the maxi mum rise in the cholesterol level was below 80 mgm only in I case the figure was high. The average was about <2 mgm. Seven cases of gall bladder disease could be studied and of these 6 were cases of chronic cholecystitis and I was a case of cancer of the gall bladder as proved on the operating table. In a cases the cholesterol metabolism could be studied both before and after operation and it was noticed that the rise in the level was not so high after the operation of removal of the diseased gall bladder. If tables are compared after the diseased organ is removed from the body in cases of cholecystitis the metabolism curve again becomes low like that of other normal people. It can be judged by comparing the graphs of patients who have been operated upon. If the rise of cholesterol is between 100 and 150 mgm the case is probably one of cholecystitis, but if the rise is more than 150 mgm one should be inclined to think it is a case of cholecystitis and this adds to the existing methods of confirming the diagnosis of chanic chalecystitus

By comparing the tables one is forced to think that the marked rise in the level of the serum cholesterol in the table shown herewith is certainly due to the diseased condition of the gall bladder. In all of the first 6 cases the rise was more than 100 mgm the minimum being 100 mgm. the maximum 188 mgm and the average 1615 mgm. The seventh case was that of a cancer of the gall bladder and in this the rise was only 75 mgm, although the fasting serum cholesterol was 300 mgm, and was due to jaundice. It is only in the chronic inflammatory conditions of the gall bladder that a marked rise in the level of

serum cholesterol occurs in the case of a new growth this was not noticed. CHARLES BARON M.D.

Ottoman R. E., and Baker J : Metastatic Staphy lococcal Infection of the Gall Bladder West J Surg 1945 53 361

The authors report 2 cases of empyems of the gall bladder as a complication of simple superficial staphylococcus infections. One was secondary to a felon of the thumb and the other followed a anc cession of bolls. Staphylococci were cultured from the gall bladder in each case. One gall bladder con tained stones but no stones were found in the other

In each patient the diagnosis was difficult because of red cells, pus cells and staphylococci in the urine. In a patient a severe pyelonephritis intervened be tween the bolls and the cholecystitis in the other a perirenal infection was suspected but it was not

Cholecystostomy was done in each case and re sulted in recovery EARL O LATRICE, M.D.

Mirizzi P L 1 The Cystic Duct in Biliary Lithiasis (Cl conducto cistico en la litinais biliar) Prense ered. argeni 1945, 38 2149

The author describes the normal anatomy and histology of the cystic duct and variations of the position of the duct under pathological conditions.

Mucostants of the cystic duct may be caused by an abnormally high registance of the sphincter of Oddi. increased mucous secretions of the extrahepatic ducts, dilatation and hypertrophy of the wall of the cytic duct.

The cystic duct may be entirely absent and in such cases the gall bladder empties itself directly into the common duct. The cystic duct may also form a junction with one of the hepatic ducts, usually the right. A double cystic duct has also been described The cystic duct may be adherent to Hartmann's pouch. Cases of primary cardnoms of the cystic duct have been reported in the literature.

A dilatation of the distal portion of the cyatic duct comparable with a river estuary may be the se quel of stenosing inflammation or functional disorders of the sphincter Such formation is of practical imnortance because a ligation of the cystic duct may produce traction on the opposite wall of the common duct and lead to an interruption of the biliary flow

Under normal circumstances the cystic duct forms an acute angle with the hepatic duct. As a result of a gallstone formation this angle may become more pronounced and interfere with the bile flow to the gall bladder Paroxysmal crises accompanying the resulting anatomofunctional hepatic syndrome may become quite serious and may produce jaundice. Scierosis of the biliary ducts in such cases distorts the normal anatomy and there is great danger of madvertent ligation of the right branch of the benetic artery

Clinical diagnosis of primary carcinoma of the cystic duct is impossible. As a rule the condition is

mistaken for cholelithiasis.

Biliary fistula of the cystic duct after an operation is usually due to a stone formation between Heister's valves. Occasionally a biliary phlegmon of the abdominal wall, without a stone formation, may bed to the formation of a fistule of the cystic duct

Lithiasis of the cystic duct is a rare condition Icterus is observed in about one-third of all the cause An inflammation of the stump of the cystic duct

following cholecystectomy without a stone formstion is relatively frequently responsible for post operative pains.

Neuromas in the wall of the cystic stump may be responsible for postoperative pains. A dilatation of the stump of the cystic duct may be followed by a concomitant dystonia of the sphincter of Oddi. Some times such conditions require a choledochodrode postomy

In selected cases abnormalities of the lumen of the common duct may be corrected by the implantation of the cystic duct into the duodenum in order to side track the bile flow. The operation may be considered in some cases of inciplent stenosing pancrestnis.

The author advocates preservation of the cystic duct after cholecystectomy not only to facilitate operative cholangiography but also to create a safety valve in cases in which an incomplete obstruction of the distal third of the common duct is present

JOSEPH K NARAT M.D.

Dameshek, W., and Miller E. B.: The Megakaryocytes in Idiopathic Thrombocytopenic Pur pura, a Form of Hypersplenism. Bied J Hemel 046

The megakaryocytes of the sternal bone marrow were studied at bloosy in 11 cases of idiopathic thrombocytopenic purpurs and compared with those of 10 normal individuals, of 5 cases of thrombocytopenic purpura associated with various types of splenomegaly and of a large group of miscellaneous bematological conditions associated with a reduction in platelets including leucemia.

Megakaryocyte counts expressed in terms of a million nucleated red cells and differential counts of megakaryocytes were made. The megakaryocytes were classified as megakaryoblasts, promerakaryocytes and mature forms, and were further subdivided into those showing granularity platelet production degenerated forms, and mitoses.

In the normal individuals, not more than 300 megakaryocytes per million nucleated red cells were present, and an average of 68.6 per cent showed platelet production. In the case of acute idiopathic thrombocytopenic purpura although the platelets in the circulating blood were rare, the megakaryocytes were increased being present in a proportion of from \$66 to 743 per million nucleated red cells However platelet production was greatly diminished and found in from only 8 to 19 per cent of all mega karyocytes. Following splenectomy, there was a striking increase in the platelet production, which was now present in from 69 to 85 per cent of all the cells, and the large masses of new platelets in the

marrow were often very striking. In the cases of chronic idiopathic thrombocytopenic purpura the megakaryocytes were considerably increased over the normal values but showed great diminution in platelet production following spienectomy extreme degrees of platelet production from the megakaryocytes took place. In splenomegaly of nonleucemic origin (carrhoels, spienic vein thrombosis, Gaucher's disease, Felty's syndrome) the megakaryocytes were somewhat increased but platelet production was normal. In aplastic anemia, lymphosarcoma acute leucemia and other diseases invading or destroying the bone marrow, the megakaryocytes were conspicuously reduced the few remaining cells being of normal morbiology.

The findings of increased megakary ocytes and greatly diminished platelet production in the marrow before splenectomy and the atriking increase in platelet production after splenectomy indicate a definite pathogenetic relationship of the splene to the disease. Idiopathic thrombocytopenic purpura is probably a form of hyperspleniam (splenic thrombopenia) in which, through a possible hormonal mechaniam the megakaryocytes of the bone marrow are inhibited from normal platelet production and delivery. The marrow findings in idiopathic thrombocytopenic purpura are sufficiently characteristic to be of diagnostic value in differentiating the disease from leucemia and other conditions associated with low blood platelet count Harou Lauruam MD.

Etcheverry M: Postoperative Eventration through the Anterolateral Abdominal Wall (Le eventra clon post-operatoria en la pared antero lateral del abdomen) Rev méd quir pot fem B Air., 1945 13: 305.

The frequency of eventration remains approximately the same from year to year it occurred in about 2 5 per cent of all laparotomies according to the author's statistics. Three main factors responsible for eventration must be considered (i) organic deficiency of the patient, either local or general, (2) technical errors, and (3) postoperative complications which interfere with normal restitu

Four conditions of the abdominal wall can be distinguished in the discussion of disruption of the abdominal wound the hypertonic and hypotomic abdomen and the strong and weak abdominal wall.

tion of the tismes.

Eventration occurs mostly in the anterolateral portion of the abdomen at the site of the fusion of the superficial and deep aponeurosis.

As far as the operative technique is concerned, 3 points are essential (1) adequate exposure, per mitting essy access and manipulation of the organs to be operated on, (2) proper selection of the zone of the abdominal wall, allowing perfect reconstruction and (3) selection of the direction of the incision with regard for the integrity of the muscular fibers and nerves.

A transverse incision seems to be logical because it is parallel to the blood vessels and nerves. Particular care must be exercised when catgut is used as suppreparative.

The author mentions three frequent causes of disruption of the abdominal wall (7) a subcutaneous or subaponeurotic hematoma attributable to in sufficient hemostasis (2) lafection of the wound, and (3) the introduction of a drain into the abdominal cavity. The irritating effect of a foreign body such as a drain is intensified by contamination of the abdominal wound by infected fluids escaping from the personnel cavity.

The author prefers a double knot to a triple knot because of the facility of tying and a lesser amount of foreign body left in the wound. If a triple knot is used, catgut is usually tied twice in the same direct ton and the last time in the opposite direction. The author prefers tying the knot in alternating directions. He also maintains that a continued suture approximates the tissue better than interrupted satures.

Colp R. and Druckerman L.: Subtotal and Pallia tire Gastrectomy for Chronic Gastric Ulcer Surgery 1945 18 573

A series of 42 consecutive patients suffering with chronic gastric uleer treated surgically is presented. The duration of the disease varied from several months to 40 years. The patients were admitted to the surgical service only when the pain was becoming more severe despite adequate treatment, when an intractable pyloric stenosis was evident, when hemorrhages had become recurrent and when the presence of a carcinoma was suspected. In the series of 42 cases of benign uleer the roentgenologist reported 3 cases as being highly suggestive of neoplasm. Of 22 cases in which the gastroscopist could visualize gastric ulcerations, 5 were pronounced malignant but were subsequently proved to be benign. An absolute achierbydraw was present in 12

The preoperative preparation of such patients many of whom are in poor general condition is out lined. At present the authors prefer continuous spinal anesthesia combined with sodium pentothal intravenously since it provides the best relaxation and exposure with a minimal amount of retraction Exploration is carried out through a median epi gastric incision and the operation of choice is subtotal gastrectomy of the Holmester type. If the lesion is so massive that resection appears imposaible preliminary jejunostomy seems a logical procedure to put the stomach at partial physioiomical rest and cause regression in size of the ulcer so that partial gastrectomy may be performed several weeks later with comparative case and safety The stomach is usually removed in a retro grade manner, and antecolic anastomosis using a short proximal loop of jejunum about 6 inches long is performed.

In 9 cases in which either a very high gastric re section had been performed or in which a marked

preoperative dilatation of the stomach increased the possibility of postoperative gastric atony a complementary jejunostomy for alimentation was done There were 6 cases in which the antrum and pylorus were removed, but the ulcer was left in suls. The so-called palliative gastrectomy has not had wide application and has one major disadvantage-the lesson which is not removed may possibly be car cinomatous. On the other hand removal of the antrum and pylorus of patients suffering from gastric ulcer almost always results in anachlity so that recurrent gastric or gastrojejunal nicer is almost unknown.

The indications for palliative gastrectomy in this series were penetrating ulcer high on the lener curvature or ulcers juxtaesophages in location. The general physical condition in a patients was so poor that an excessively high resection necessary to re move the ulcer would have been extremely hazard gus

The postoperative course and complications are described. In the series of 4s consecutive gastrec tomies for gastric ulcer there were a deaths.

Poth E. J. Ross, C. A. and Fernandez, E. B : An Experimental Evaluation of Sulfagoxidine and Solfathalidine in Surgery of the Colon. Surgery 1945 18 529.

The study made by these authors shows sulfa suxidine and sulfathalidine to be valuable adjuvants in surgery on the colon of the dog. The indications are that the so-called aseptic methods of anastomosis should be used whenever possible, but it is evident that an open technique may be undertaken with a considerably increased degree of safety observations support the satisfactory results obtained when man is treated in a similar manner

The reaction, as revealed by the amount of edema of the omentum adherent to the line of suture, is significantly less when the bacterial flora is modified by the administration of the drugs. The most elearcut evidence of the value of these drum is re vesled by the results which followed the method of open anastomosis, wherein no effort was made to prevent fecal soiling of the operative field. Even though the degree of spillage was much greater following the administration of sulfasuridine because of the semifluid nature of the contents of the bowel, there was a striking difference in the operative mortality and morbidity. Forty-three per cent of the control animals died of generalized peritonitis due to disruption of the line of sature. One hundred per cent of the control animals showed gross leakage at the line of auture. These observations are in contradistinction to absence of death and lack of gross leakage through the suture line when the animals had received sulfasuxidine and sulfathalidine. Furthermore in the control experiments there was scute inflammation and little evidence of healing and repair by the fifth postoperative day Follow ing drug therapy the inflammation had subsided and

the tissues had undergone orderly repair and healing. BENJAMIN GOLDMAK, M.D.

Patton, E. P : Proctological Problems of the Pedi atrician. J Polist, S Louis, 1945 27 532

The etiology of constitution, painful defecation frequent small stools, and bleeding per rectum in infancy and childhood is often an abnormality or a disease of the anus or rectum which can be deter mined by proctologic examination.

A frequent cause of constipation in early inlancy is an incomplete dissolution of the membranes be tween the bindgut and the proctedeum. This may be manifest at birth, but may not develop to a de gree of marked obstruction for days or even weeks The opening may be adequate at first, but as time goes on, folds of mucosa of the segment of rectam above the constriction overlap across the lumen. thus forming a valve A stenosis, in the form of a disphragm or ring of thesie, can be overcome by one or more gentle dilutations with a lubricated, rubber

covered finger The usual cause of pamful defecation is an anal fissure or an area of proctitis. In an infant or small child an electric otoscope using a large speculum serves as a useful proctoscope. Anal fractices are readily visible. Proctitle is seen as a red, congested area of mucosa contrasting with the pale pink, nor mai tissue around it. A regimen to produce small soft stools is necessary to beal a fasture or proctitis. This involves the establishment of two regular toilet times daily the occasional use of a suppository or enema, the intake of generous quantities of water stewed fruits and vegetables, the temporary use of combinations of agar and mineral oil by mouth, and anesthetic cintments locally. The healing of fisaures and proctitis is aided by the topical applica

tion of silver nitrate. Frequent small but otherwise normal stools may be caused by anal fissure, proctitis, or a local der matitis The latter may be due to a fungus infection, pinworms, scabies, cryptitis or papillitis. The treatment of this complaint is dependent upon the

The many causes of bleeding per rectum are well known. The causes of rectal bleeding visible through the proctoscope are fissure, proctitis, polyp, or ulcer

(nonspecific or amebic) Prolapse of the rectum may be caused by a polyp.

but it is usually due to a redundant mucous mem brane. In the immediate treatment concern should not be so much for prompt reduction as for perms nent retention after reduction. If prolapse is allowed to persuat for hours, or even until sponts neous reduction with simple recumbency takes place, the resulting edema and local submucous reac tion is beipful in producing thickening and fibrous tissue which will belp in permanent retention if the stools can be kept small and smooth enough to pass easily while mucosal edema is subsiding Various methods are proposed for maintaining reduction, such as continued recombency elevated hips, or

strapping the buttocks together with adhesive tape. The anti-constipation regime as outlined before must be instituted concurrently. If conservative treatment fails to prevent recurrences a sclerosing solution may be injected in the submucous tissues.

Although megacolon is not primarily a proctologic problem, some cases can be relieved by systematic rectal dilatation with graduated dilators.

Perirectal abscess fistula in ano and hemorrhoids in childhood are managed as in later life

Alecha J M Carpanelli, J B and Ferreira J A.; Amebic Abacesa of the Liver Opening into the Perlioneal Cavity (Abacesa amebiano hepatico ablerio en cavidad perlioneal) Rev. 4x méd argent 1945, 59 1043

Amelic abscess of the liver is the most frequent localization of ameliasis outside of the intestine An analysis of 14 poy cases of ameliasis showed hepatic abscess clinically in 486 per cent but autopry showed it in 36 per cent.

The diagnosis is often not made until perforation occurs although a careful study of the history should give indications of the true diagnosis. X ray examination may show malformation of the liver especially of its diaphragmatic surface and may also show peritoncal effusion. Rectosigmoidoscopy may be useful in showing dysenteric ulcers. In 90 per tent of the cases the pus in the abscess is aseptic. Amehae are much more apt to be found in tissue caretted from the walls of the abscess.

A case is described in a man of 37 years in whom the diagnosis was not made until operation although he had a rather typical history. He had been treated in a clinic 3 years before however and neither laboratory nor roentgen examination had given any indication of the true diagnosis. When he was admitted with the picture of acute peritonitis a diagnosis of perionated acute cholecystitis was made. Operation showed the true condition and the abscess was evacuated and emetin treatment begun. The amebae disappeared from the feces after the first series of emetin and the patient made an un eventful recovery.

Although the pus of the abscess was aseptic the diagnosis of its amebic character was made from the lack of any history or evidence of pyogenic infection the macroscopic appearance of the abscess and its contents the relative senousness of the case and the slight postoperative peritoneal reaction, the presence of the vegetative forms of amebae in the feesace of the vegetative forms of amebae in the researce of the vegetative means of the disease.

Some surrecoms use mentin intranspiratoneally dur

ing operation, but the authors do not believe there is any logical indication for its use in this way

AUDREY G MORGAN M.D.

Brunschwig A.: Radical Resections of Advanced Intra Abdominal Cancer Ann Surg 1945 122 923

Progress in supportive treatment of the surgical patient permits of the extension of radical surgical attack upon advanced abdominal cancer. Experiences in a series of 100 patients revealed that effective, albeit in some instances brief palliation was afforded in 35 per cent and an appreciable and prolonged palliation was achieved in an additional 15 per cent of the series. Given adequate conditions, a more radical attitude in the surgical treatment of advanced abdominal cancer would appear justifiable.

#### GYNECOLOGY

#### UTERUS

Clift A. F. i Observations on Certain Rheological Properties of Human Cerrical Secretion Free E. Sec. M. Lond. 1915, 39, 1

Cernical mucus the most other secretions of the body is not a true fluid because it does not flow at a steady rate under con tant pressure. Lutther more when pressure is increased the rat of flow does not increase proportionately. Such secretions are complex systems characterized by properties such as anomalous secousty claticity th wells toty. Spinnharkest and adherivenes. A stuly of such physical properties; called theology.

Experimental evidence and num rous clinical observations suggest that the theological properties of human cervical mucus undergo a cyclic variation in the menstrual cycl and furthermor bear direct relation to ovulation to penetrability of cervical mucus by permatozoa and to pregrance

This auth it has furcted his attention primarily to the study of two hithert unreconnect declored; projecties of cervical mucu main by, flow cla ticity and Spinnharkeit. When a material showing flow cla ticity i caused to flow along a tube and the pressure is suid fenly rel ased the material recoil towards its original position. The property is accurately measured in the mensionscope as in triment which consist seventially of a graduated gla capillary tube. One code of the tube it open the other his triphtly on to a systeme A small safe table for the control and sudden release of pressure is interposed between the syringe, and the main tube.

Spinnbarkets is the capacity of legible to be drawn into threads. The most suitable linglish term now available is shown to "It is a projectly of cerman mucus and is capable of accurate measurement. The text is carried out by drawing away a coveral p placed on a blob of mucu and mea using in cent meters the thread thus produced.

The author stresses the foll aine pant a spice

requirite of interpretation of result

The cervix must be health; with ne pathological tear marked erosion or endoc rote to
 Contamination with blood should be reduced.

t aminimam

- 3 The pecimen must be collected from the cervical canal not from the vaginal vault or from the external cervical os.
- 4. Neither douching nor coitus must have taken place during the 48 hours preceding collection.
- 5. No antiseptics should be used in collecting the sample
- 6 The test for flow-elasticity (elastic recoil) hould be performed within 20 minutes of collection of the sample.
- The cervical mucus of 26 women showing normal menstrual cycles wa studied. Seven of these w men

were seen more than once, 3 were studied for a least one complete evels and 2 became preparant during observation. How-elasticity and Sphaldar Leit were measured. The amount of mours secretation of the macro-copic appearance and the number of leurco; tes contained in the specimen were also noted. These properties were carefully correlated with the time of the menstrual cycle or pregnancy and they supply two new theological tests.

A throboxical test for ovulation in woman is described. The sample of cervical mucus is muna and homogeneously translucent. Flow-clustely subspanning that maximum. The cellular content is minimal. At this time penetrability and longerity of strematics are retasters.

A theolysical lest for preparancy in somato is described. The sample of cervical mucus is thick and bomogeneously opaque. The mucus is difficult to draw into the mentioscope and there is about complet absence of flow-classicity and Spinolarical.

These rheological phenomena and tests should prove of value in the recognition of orulation and anovulator, cycles in the investigation and treat ment of some forms of sterility (cervical hostility) in various types of orarian dysfunction, and in application as access in tests for pregnancy

L. J. MTS TALBOT M.D.

Curtls, A. II : Hypertrophy of the Uterus. In J Old 1945 to 745.

The u ual symptoms of hypertrophy of the uterus are prolonged or excessive menstruation pelver pressure with more or less aching discomfort, and increased vaginal lischarge.

Examination reveals an enlarged uterns which is usually heavy often tetrologistical, and difficult to differentiate on bimanual examination from adomysms of the uterus or diffuse enlargement from deeply bened myomas. Di rentation from air comma d the lody of the uteru is sometimes difficult occasinally even after examination of uteriar currentings in the cases of hypertrophy with marked on longitally hyperpla is

It tological diagnost of the various types of uterine hypertrophy is includated by differential time. With routine hematoxylin and coolin atamenlarged and thickened blood revest and the amount of perivacular connective tissue are readily reconized but accurate determination of the resultiproportion of connective tissue and muscle cells is not simple. Varietnome stain similar to the Mailory stain helps to solve this difficulty.

The more enlarged uterl are studied the more apparent it becomes that variou gradations of hypertrophy are encountered in most instances and that pure subinovalution or true diffuse hypertrophy of hypertrophy to metritis or to enforcing

d turbance i unusual

Curettage may be required for differential diag nosis, and strangely enough, it is sometimes bene ficial. If more important surgical intervention is required, one should hesitate to perform corrective operations for uterms displacement in these cases unless childbearing is an important issue removal of the oflending organ by subtotal or complete hyster ectomy is the procedure of choice

#### ADNEXAL AND PERIUTERINE CONDITIONS

Ziegler E. E.: Bilateral Ovarian Carcinoma in a Fetna 30 Weeka Old Arck. Path. Chic. 1945 40 270.

This is a case report of a carcinoma which apparently was a dysperminoma arising from granulosa cells in a fetus weighing 1,340 gm, and estimated to be thirty weeks old

At the routine autopsy the ovaries were slightly enlarged and graytth pink in color. They aroused no special interest during the autopsy and the tissues were removed and sectioned routinely. Histological examination however showed that the entire substance of each gland was practically replaced by car commutous tissue. The cancer cells contained numer ous mitotic figures. Scattered through the neoplasm were numerous primitive grantian follicles. In some places the granulosa cells accmed to show stages of transition into neoplastic cells. This gave the impression that the tumor was a granulous cell carcinoma. The tumor cells themselves, however resem bled those of dysgerminoms, and there was a delicate tumor stroma between the masses of tumor cells which also resembled the stroms of the well known dyagerminoms. There were no gross or microscopic evidences of extension or metastases.

The mother of this infant is living and well and has since given birth to a full term well developed,

normal appearing infant.

The occurrence of neoplasia in childhood in in fancy and now in fetal life seems to lend weight to the opinion of those who believe in the Importance of hereditary as opposed to environmental factors in the causation of cancer it seems to midcate that at least some cancers may occur without the operation of extremic environmental factors.

SAMUEL J FORELSON M.D.

#### MISCELLANEOUS

Grailet, H. E.: The Use of Prostignine in the Treat ment of Amenorrhes and as a Pregnancy Test (De l'emploi de la prosilgnine dans le traitement de l'amenorrhée et comme test de grossesse). Res f gra. dels 1042 40-150.

Emmenagogues such as apiol ergot, and yohim bine were formerly used to start menatruation because they produced congestion in the pelvic organs. They have been replaced by sexual hor mones but recent studies again focus attention on the rôle of hyperemia in the mechanism of menstrus tion. It has been shown that hormones produce histological transformation of the uterine mucoes which the older drugs were not able to cause, but the ability to create hyperemia and uterine bleeding is common to both groups of drugs Estrogenic hor mones have a double effect (1) a specific action and (s) a nonspecific action related to the phenomenon of hyperemia. Both male and female sexual hor mones display a vasomotor effect, attributable to the ability to liberate a certain amount of acetylcholine which acts on the blood vessels through the parasympathetic system Acetylcholine is produced in situ and not in remote places. Such effect is of short duration not exceeding 12 hours because a hydrolytic disintegration of the acetylcholine occurs under the influence of the enzyme cholinesterase present all alone the nerve fibers.

Many authors consider that the menstruation results from a vasoditating reflex comparable with erection. Retardation of the menstruation without apparent cause may be attributed to a nervous factor responsible for an insufficiency of the vascular response with a glandular system intact. To remedy such condutions prostignate has been suggested instead of acetylcholine because it acts on the parasympathetic system by inhibition of the cholinesterase without the dangers associated with acetylcholine. In the manner a rapid disintegration of acetylcholine in the tissue is inhibited and thus a

nterme hyperemia is facilitated

The author employed prostigmine in 86 patients and could check the results in 75. A menstrual delay

of from 5 days to several weeks was recorded in the histories. The material consisted of 30 cases of pregnancy to monpregnant cases in which endocrina or organic disorders could be excluded and the amenorrhees had to be considered as accklental, and the remainder in which the patients had probable or

manifest endocrine disorders.

The author concludes from his investigation that three consecutive injections of proviginite in women who usually have a normal meastrastion are followed by bleeding, usually typical meastral bleeding. In women in whom an organic or endo-cane disorder h suspected such prompt result is considerably less frequent and usually appears only if the injections coincide with the luterial phase. No uterine bleeding occurs if amenorrhes is due to preguancy. Therefore prottigmine injections may be used as an early diagnostic pregnancy test. If no bleeding follows a injections of prostigmine in patients without any evidence of endocrine or organic disorders. He no possibility of pregnancy though the proposition of prostigmine in patients without any evidence of endocrine or organic

considered

The patient should be informed that the injections

will not provole an abortion.

In 14 nonpregnant patients treated with postignaine a bloody show appeared within 6 days after the last injection in patients with amenories postpartum the time which elapsed between the injections and the bleeding was long enough to create doubt as to the efficiency of protrimine.

The author expresses doubt as to the efficiency of prostlemine in amenorrhea caused by endocrate disturbances.

#### OBSTETRICS

#### PREGNANCY AND ITS COMPLICATIONS

#### Bernstine, J. B.: Vaccination during Pregnancy as a Prophylaxis against Puerperal Infections Med Clin N America 1945 29 1495

The investigator undertook to culture the type of organisms commonly found in puerperal infection test their effect on laboratory animals and by means of a vaccine made from the cultures, clevate the immunity of the pregnant woman to such infections.

Cultures were taken from the cervix and endocervix of pregnant women with a sterile cotton swab placed in a tube of blood agar and subcultured within 30 minutes. The culture media consisted of s per cent defibrinated horse blood agar plates beef infusion broth, #H 76 and plain 25 per cent infu sion agar plates and alants. The common organisms found were the staphylococcus albus streptococcus viridans the diphtheroids nonhemolytic streptococcus and hardling authorities.

After a vaccine was prepared as explained in detail in the original article a groups of mice were moculated with various strengths of the vaccine Following the study on mice, to female patients in the childbearing period were selected. No reactions occurred in this group therefore 471 patients attend ing the maternity clinic at Jefferson Medical College Hospital Philadelphia, were moculated There was no particular selection of the patients and later at the time of delivery it was not revealed which patients had been inoculated

The initial injection was 1 minim with subsequent injections of 4, 8, 12 and 16 minims. The number of injections varied from 8 to 30. The majority of patients received their injections from the fourth to ninth month. There was a noted absence of reactions in these women.

In this series of vaccinated patients, 4 , per cent were morbid during the puerperium as compared with the nonvaccinated group whose morbidity was 17 1 per cent. This study concluded a series of 973 patients who were vaccinated 502 having been reported upon in preceding papers.

CATHERDOR B HISS M D

Duran A.: Axial Torsion of the Myomatous and Pregnant Uterus (Torsion axial del utero mioma toso y gravido) Bel Sec chilene ebst gin 1945 to rig.

Axial torsion of the myomatous and pregnant uterus is very rare. The author has found only 2 cases in the literature before he encountered the one reported in this article. This case was in a woman of 38 years who was found to have a nodular myoma of the uterus complicated by a pregnancy of 11/4 months. The myoma was removed the denuded surface covered with bladder peritoneum and the wound sutured The woman made a complete re

covery and the pregnancy continued without interruption. The other 2 cases are reviewed briefly

The name axial torsion is not really correct as this would indicate a torsion of the whole organ around its axis while as a matter of fact there is a rotation only of the body of the uterus around the supravaginal part of the cervix which is lengthened and softened by the existing conditions. The rotal tion may be to the right or left and may be as much as 180 degrees, so that the anterior surface of the uterus looks backward. Torsion of a nonpregnant myomatous uterus may be as much as 460 degrees Factors in the torsion are the weight volume and site of implantation of the tumor and the softening and elongation of the 1sthmic portion of the uterus brought about by the pregnancy The torsion causes a sudden intense pain irradiating over the whole abdomen, accompanied by syncope a small rapid pulse vomiting cold sweat, and dyspnes. The tem perature is normal and there is dissociation between the pulse and temperature. Abdominal paination reveals muscle rigidity and intense sensitiveness. In cases in which the torsion takes place gradually the symptoms are slight.

Operation should be performed as soon as the diagnosis is made detorsion is generally not difficult the uterus may be fixed in position by Passeron s hysteropexy or Pestalozza s pelvic hysterectomy the myoma removed and the denuded zones covered with peritoneum. If the torsion has caused serious circulatory disturbances such as extensive extra vasations of blood infarcts or zones of gangrene the uterus must be removed. If no great circulators changes have taken place and the myomectomy has left the wall of the uterus in good condition the preg nancy may continue However if the site of im plantation of the myoms is very large or serious nutritive disturbances of the wall of the uterus have taken place the uterus may rupture

AUDREY G MORGAN MLD

#### PUERPERIUM AND ITS COMPLICATIONS

Rosenblum, G. Melinkoff E. and Fist IL S: Early Rising in the Puerperlum J 1m M Ass 1045 120 849

The practice of early rising of parturient women dates back to ancient times. Although it was recently stimulated by the wartime shortage of obstetric beds it did not arise from that emergency The nuerperlum or time of rest given to women in childbed has varied more widely in the customs of different peoples than any other feature of that great physiological function of woman

The practice of early ambulation of surgical pa tients now a widely accepted procedure and advocated by hundreds of articles in the American and foreign literature must be considered intimately related to the practice of early puerperal rising. The objectives and underlying principles of the two are identical.

With a background of favorable evidence in the literature the task of studying early ambulation in the puerperium was begun. At the outset it was realized that there would be objections both from natients and from the medical profession to the practice of early ambulation. The following objections arose during the course of their study

The objections of doctors were (1) fear of medicolegal consequences, (2) fear that episiotomics would break down (3) fear that there might be too much strain on the pelvic floor resulting in prolapses and retroversions, (4) fear of excessive post partum bleeding and (5) fear that patients would

not approve of early rading The objections of the patients were (1) that the procedure was unfamiliar to them, therefore they were not sure it was good (2) that they needed rest and it musht tire them too much to get up (a) that they were too weak to walk, (a) that arising might make them bleed too much and (5) that they might

break their stitches. A group of 382 obstetric patients who were studied were divided into three groups as follows (s) 227 early risers ambulatory on the first or second post partum day (2) 100 intermediate risers, ambulators on the third or fourth postpartum day and (1) 220 late risers ambulatory later than the fourth nost partum day

The study of bladder function showed a close similarity of the catheterization curves for the three groups. The contention that early puerperal rising may cause excessive bleeding is disproved by the statistics, which show actually less frequent abnormal bleeding in the early group than in the late group Involution of the uterus was uniformly good in all groups. The fear that early rising would cause a breakdown of episiotomy or abdominal wound incipions is likewise unfounded, only I instance of perineal skin separation occurring in the entire series, and this in a patient in the late rising group. More efficient mobilization of the bowels was evident as more than three times as many spontaneous bowel movements occurred in the early as in the late group

The total number of complications in the entire series was very small, and there was no significant difference among the three groups. As there were no patients having emboli or thromboses in the entire series, the contention of many previous authors that late rising fosters these complications was not proved in this series. However a study of a much larger series might possibly reveal a lower incidence of these complications in the early risers.

The claim advanced by some obstetricians that

early rising may cause later prolapse and retrover sions is also disproved. Of the early risers examined at I month and at 6 weeks 18.7 per cent had either a midposition or retroversion of the uterus, while 34 6 per cent of the intermediate and 244 per cent of the later risers had the same positions - relatively similar totals. This indicated that early rising cares no significant alteration in the position of the uteres. at least within a period of from 4 to 6 weeks follow ing delivery Prolapse did not occur in any patient in the entire series.

The nurses working in the obstetric department reported a decided reduction in the amount of nuring care required for patients rising early. The noted better morale and less discomfort in the

group

Particularly favorable are the reports concerning cesarean sections in which cases less abdominal distention and discomfort, and a much more rapid one valescence was noted.

No patient in either the early or the intermediate group offered any criticism concerning the early rusing in fact, the majority exhibited enthusiasm. The multiparas especially were impressed, statur that they felt better and stronger than they had after previous confinements, when they had speat a period of from 7 to 14 days in bed.

CHARLES BURGS, M.D.

#### MISCELLAMEOUS

Van Watenen, G.: The Optimal Mating Time for Prenuncy in the Monkey Enterinder 1841. \$7 307

Since the rhesus monkey (macaca mulatta) is the laboratory animal of choice for the study of the physiology in reproduction, any knowledge concerning the optimal mating time for pregnancy is of considerable interest.

The author reports on a series of observations extended over a 5 year period on monkey breeding During this study a rigorously standardized plin for mating at a particular time in the mensurual cycle was used

The routine procedure was to place the female on the eleventh day of her menstrual cycle in the cage of a male for a period of forty-eight hours. Thirty two per cent of such matines resulted in pregnancy Another forty-eight hour mating starting on the thirteenth day of the menatrual cycle resulted in pregnancies in 24 per cent of the cases.

Another series of a5 monkeys were studied and their mating date was delayed to the seventeenth day of the menstrual cycle. These animals were mated more than an average of three times each, eighty times in all, but at the end of a months only I pregnancy had been effected. In contrast, when the remaining 24 monkeys then were mated on the eleventh day of their next cycle 7 of them became

pregnant. The author concludes that in this particular monkey the period between the eleventh and thirteenth days of the menstrual cycle is the preferred time for HARRY FIXIDS, M.D. mating

## GENITOURINARY SURGERY

#### ADRENAL KIDNEY AND URETER

Huddins, C. B., and Scott W W : Bilateral Adrena lectomy in Prostatic Cancer Ann Surg 1045 112 1011

Abundant use of plasma transfusions seems to be of great importance in the prevention of circulatory collapse following adrenalectomy in man.

The author states that inadequate therapy after adrenalectomy in man results in early hypernyrema and hypotension the carbohydrate metabolism is not drastically disturbed. In the adrenalless man adequately treated with plasma adrenal cortical extract, and desoxycorticosterone acetate these effects were not observed but addisonian prementa tion occurred on the sixteenth postoperative day

and was progressive

Complete adrenalectomy in castrate man results in a reduction of 17 ketosteroids to values less than 2 mgm, excreted in the urine daily total ketonic, and alpha fractions are greatly diminished. Urinary androgens as measured by the comb-growth tech nique are absent. There is a continued excretion of small amounts of estrogen. In a man who survived complete adrenalectomy for 116 days there was a sustained reduction of alkaline phosphatase activity of the serum but the prostatic cancer progressed although apparently at a retarded rate. The inection of desoxycorticosterone acetate elevated the blood pressure to normal levels but hypertension did not occur with massive doses

The extragonadal androgenic depot in man is the

adrenal.

Adrenalectomy is not a practical method of treat ment of the failure-group of patients with prostatic cancer treated by antiandrogenic methods

Three factors, whose presence and significance vary in the human prostatic cancers may be stated (t) the testicular androgens (2) the extragonadal depot and (3) androgen-dependence or its opposite adrogen independence. It is not vet possible to de fine androgen-dependence or independence in chemical terms. IOUN A. LOUY M.D.

Horts, J S.: The Question of Origin of Grawitz Tumora (El problema del origen de los tumores de Grawita) Arch. espan urol 1945 2 115

There is no unanimity of opinions as to the origin of Grawitz tumors but at present there is more and more tendency to accept the renal theory Modern biological studies of the functions of tumors originat ing in endocrine glands justify a revision of the older theories pertaining to the origin of Grawits tumors.

A priori we may consider Grawitz tumors as originating from a normal structure of the adult kid ney Apparently such neoplasms do not derive from intrarenal inclusions of the suprarenal glands There are arguments based on morphologic and bio-

logical considerations which tend to show that hy pernephroma does not originate from aberrant

suprarenal glands within the kidney

Undoubtedly there is a great microscopic similar it) between such tumors and the suprarenal cortex. In many cases it is impossible to distinguish microscopically a hypernephroma from the suprarenal cortex in both, the fat and glycogen are present in very small amounts or they are absent entirely cellular protoplasm is scanty and fusiform forma tions are present. Ewing maintains that nondiffer entiated cells frequently found in a suprarenal car cinoma, are not present in the renal glands.

Sarcomatous structures may be present in Grawitz tumors as well as in the suprarenal cortex. The author shares Ewing's opinion as well as that of Apits who maintains that both Grawitz tumors and those of the suprarenal cortex may have a sar comatous structure which derives from epithelial cells the renal epithelium and that of the suprarenal

glands are of mesothelial origin

Frequency of papillae and lucid spaces is charac teristic for parenchymatous tumors of the kidney while in corticoruntarenalomas they are very rare Such formations in suprarenal cortex tumors are of glandular origin Under low power both kinds of tumors may look identical but under high power cells of renal tumors show a typical veretative aspect only the exoplasm is stained while the remaining cytoplasm remains colorless. Large fat droplets may be seen in sections of Grawitz tumors stained with Sudan III while the droplets are very small in The vegetative aspect of corticosuprarenalomas. cells in renal tumors is caused by the accumulation of glycogen That cellular formations are practically reduced to cytoplasm in corticosuprarenal tumors cannot be denied but according to the author's connon such images are secondary

The fact that hypernephromas do not produce alterations of the sex characteristics of the host is interpreted by some writers as an argument against the suprarenal theory. Not all tumors of the supra renal cortex are accompanied by such modifications. From the hormonal point of view the cortical tumors may be divided into (1) those which do not produce hormonal changes (2) those which are accompanied by an excess formation of estrogens, (3) those with a symptomatology related to the excessive production of metabolic steroids and (4) those accompanied by an increased excretion of androgens and steroids. To the author's knowledge not a single case of renal hypernephroma with virilism has been reported in the literature.

The presence of numerous vacuoles in suprarenal tumors but not in hypernephromas is stressed

Contrary to the rarity of aberrant suprarenal nodules of the kidney aberrant Grawitz tumors are relatively frequent.

The author believes that there are sufficient arguments in favor of the theory which claims that Grawitz tumors do not originate from suprarenal tissues.

Renal hypernephroma belongs to the group of neoplasms of the endocrine glands characterized by the presence of lucid cells such as benign corticosuprarenal tumors, luteinomas or hypernephromas of the ovaries tumors of the interstitial gland of the testes, and parastrumas.

Hypernephromas of the kidney are sometimes accompanied by hypertension but it has been pointed out that no definite relations exist between these two conditions hypertension may persist after nephrectomy has been performed on account of the

presence of a Grawitz tumor

Hypernephromas possibly originate from myoepithelial formations described by Goormaghtigh, who considers them as regulators of the circulation within the glomeruli. Joseph K Nahar M D

Santaella, R. A. 1 oluminous Pyonephrosis and Ita Treatment (Las pionefrosis vol minosas y su tratamiento) irch espan ural 1945 2 2

The author advocates a nephrectomy in two stages in the treatment of extensive properphrosis. His clinical observations and anatomorpathological studies demonstrated the advisability of such staged procedure. Perifocal scientific reaction safeguards against a spreading infection by establishing a defemitive blockade. Lauaily 1 month is allowed to eliapse between the first stage which consists of nephrostomy and insertion of a Pezzer catheter and the second stage, the nephrectomy proper. The operation is performed only if the functional capacity of the kidney in good. The hillus is ligated en masse Frequently the author leaves a clamp on the pedicle for a wresh.

Six cases in which two stage operations were performed are described in detail

TORREST & NARAT M D

Castro E P: Renal Tuberculoma (Tuberculoma renal) Arck espon and 045 50-

The author reports a case of renal tuberculoma in a 33 year old man who had repeated attacks of pain in the hypogastrium, combined with a great of pain in the hypogastrium, combined with great painter the application. The painter has been aftern the application of the painter had been as completed and the state of the combined with the combined with the combined and the painter had ministration of pyridium. Three combinates the administration of pyridium Three combinates the patient was admitted to the box pital. \( \text{\text{ny}} \) studies decised a dense homogeneous, well circumstribed shadow extending from the right hillum region to the diaphragm. There was a clear space in the center of the shadow. Hematological and bacternological studies established the diagnosis of pulmonary abscess. The patient was trrasted with short waves.

The expectoration and fever subsided and the second roentgenogram showed evidence of cicatrization of the pulmonary abscess and the existence of bronchiectasis in the right lower lobe. The patient complained of vague pains in the left recal region and the epigastrium. The urine contained a large amount of pus. Chromocystoscopic examination showed a normal function of the right killery while after the injection of indigocarmine only very pain failed was excaping from the left ureter Retrograde pyleography showed a large cavity above the upper callys, with irregular outlines after instrument urography an image of the cavity in the left killery was obtained.

A nephrectomy was performed with great difficulty on account of adhesions around the upper pole of the kidney. The patient made an unerventful recovery.

The histological examination revealed a tuberuloma of the kidney with numerous Langhans' gant cells, epithelia cells and lymphocytes. There was an intensive sciencide reaction. The glomeroll kad undergone a hyuline degeneration. Extensive necrotic zones were spread throughout the entire renal tissue in the involved region.

The symptomatology and the roentgenographic studies pointed to a renal neoplasm. The inspection of the extirpated kidney also suggested a tumor

rather than renal tuberculosis.

A check-up 2 years later showed the patient to be in perfect health Joszes K. Nakar M.D.

Gorro A. P : Partial Nephrectomy (Nefrectomia parcial) fresh explor grad 1945, 1 29.

A partial nephrectomy is indicated when a cur conscribed area of the kidney is involved the remaining parenchyma appears normal, and the ercretory prelouteteral portion is not affected. An excretive mutilation of the organ in such cases is not justified.

Partial nephrectomy advocated by a number of older writers, was later discredited on account of operative or postoperative henorrhages, and the formation of obstibate urinary fixulas which required an ultimate extingation of the organ. Furthermore, improper indications such as the presence of a malignant necolasm or of tuberculosis of the kidney also discredited the operation.

Recent advances in prological diagnosis, such as prographic studies, and improvement of the tech-

moue rehabilitated the operation.

Experiments on animals show that a portion of the renal partnethyma corresponding to one-fourth of the entire amount of both kidneys is sufficient for the survival of the animal. An entirpation of a portion of the kidney does not unfavorably after bet rather improves, the function of the remaining part of the kidney.

A decision to resect only one part of the kilosy cannot frequently be made until the surpros is afte to inspect the organ. Conditions of the blood supply and permeability of the pyrioureteral system are the most important factors to be considered. Aortic arteriography before the operation may furnish valuable information as to the blood supply to the kidney Pyelography furnishes information as to the condition of the excretory pyeloureteral apparatus.

Partial nephrectomy is indicated in in partial hydronephrosis located at one of the poles of the hidney. If lesions caused by a stone are extensive, a simple extraction of the calculus does not assure anatomic restitution of the involved parenchyma and in such cases a partial nephrectomy furnishes excellent results because it prevents an extension of the inflammatory process. A partial nephrectomy is indicated if a larve solitary cyst is present.

If a hydatidiform cyst does not communicate with the excretory ducts, a partial resection of the kidney may be considered. If in a polycystic kidney the changes are confined chiefly to one portion of the organ, the affected area may be removed and the cysts disseminated over the surface of the kidney.

may be destroyed with the cautery

Sometimes abnormal blood vessels interfere with pyeloureteral evacuation and in such cases a section of the abnormal blood vessels which may lead to an ischemia of the corresponding part of the kidney may be avoided by a prophylactic partial nephrec tomy. Otherwise a septic necroblosis may result

If a destructive renal infection is confined to one portion of the organ, the affected area may be re

sected and a drain inserted.

Only on rare occasions is a partial nephrectomy indicated in renal tuberculosis. This may be the case if the infection affects a kidney with a double preloureteral system which permits a functional and romigeographic study of both portions of the kidney. Such studies may reveal an integrity of one

part of the kidney

Anomalies of the renal pelvis with or without infection may show that two parts of the kidney function independently of one another. In such cases a plastic pycloureteral operation, when there as congenital anomaly may supplement a partial reaction of the kidney. Such an operation may be considered if a benign neoplasm involves only one part of the kidney.

In many cases of injury of the kidney a partial

resection of the organ is justified

One of the drawbacks of a partial resection is the hemorrhage this can easily be stopped with the electrocautery. The second drawback is the difficulty encountered in the determination of the extent of the lesion. Reentgenographic studies are

extremely valuable in this respect

A few essential points in the technique must be the tin mind. The blood vessels supplying the portion to be resected should be ligated prior to the resection, especially if one is dealing with an abound kidney. Many authors described a technique of approximation of the wound edges. However in many instances the wound in the kidney cannot be closed without an insertion of a flap consisting of muscle tissue and aponeurosis. Such portions of the tissues may be obtained from the external oblique muscle. Diffici lites in approximating the edges are encountered when a transverse or a wedge shaped

incusion is made in the kidney. The inserted muscul loaponeurotic strip is kept in place with interrupted catgut sutures. The author uses interrupted catgut sutures for approximation of the edges which transfix the parenchyma and the fibrous capsule.

Efficient extrarenal drainage for from 8 to 12 days provides evacuation of the extravasated urine. Otherwise an infiltration of the soft tissues with

abscess formation may result.

The author performed a partial nephrectomy on to patients. He encountered the following anatomic abnormalities a superior polar artery both superior and inferior polar arteries double renal pelvis, and a normal kidney with a double pelvis and ureter. The following pathological conditions were found pythosphatic indection hypoplasia with a complete double ureter tuberculosis of a kidney with a double pelvis and ureter infected hydrone phrosis with a double pelvis and ureter infected hydrone phrosis with a double pelvis calculous pyonephrosis with a double pelvis lithiasis with infection tumor of the kidney, hydronephrosis inferior polar artery circumscribed dilastion of a calyx and traumatic rupture of the kidney.

In 5 cases transparenchymal drainage of the renal pelvas was employed in 4 cases the unine was escaping from the lumbar incision for a few days following the operation. In 3 patients the urinary discharge stopped spontaneously between the fifth and tenth postoperative days while in the remain ling 3 cases the discharge lasted from 3 to 4 weeks In 1 patient a urinary fistula opened and closed repeatedly for a few months until a small stone was expelled spontaneously. In 1 patient symptoms of an acute pyelonephrite infection developed. The condition was attributed to a premature removal of the intrarenal drain on the tenth postoperative day Following the introduction of a ureteral retention eathers the infection subsided in so days.

TORKPR K. NARAT MLD

Frostad H: Urinary Stasis and Pains after Cyst oscopy with Catheterization of the Ureters. Acta chir scand 1945 98 546

Frostad studied of cases in which preliminary intravenous pyelography excluded utinary tracticalcula and in which pain or colic followed retrograde pyelography. After ureteral extheterization patients frequently complain of pain, and the urine from one or both ureters is bloody. Postcystoacopic intravenous pyelography demonstrated a characteristic urinary stass on the affected side. In 3 cases removal of a blood clot projecting from a ureteral ornice resulted in immediate censation of the pain. In the series cases with reduced renal function were excluded.

Protuneteral catheterization pain usually starts in one or both lumbar regions and in 2 to 3 hours gradually spreads downward along the course of the ureter to the inguinal regions. The pains may vary in intensity corresponding to ureteral peristales. They seldom begin quite suddenly as in calculous. 112 They colic, but begin and decrease gradually conc. out negin and decrease gradually and usually begin a few hours after completion of the usually begin a new nours after completion of ind-cystoscopy Of the 95 patients, 33 had postcathcystoscopy Of the 95 patients, 33 had postcath-eterization pain. Pain usually occurred when bleed eterization pain. Fain usuary occurred when been ing was most excessive during collection of the ing was most excessive during collection of the ureteral catheter specimens. A fairly constant reureters; catheter specimens. A samy constant re-lationship between the intensity of the pain and the ationship between the intensity of the pain and the amount of bleeding during collection of the speci

Of the 33 patients with postcathetenzation pain, mens was present. or the 33 patients with postcatheternation pain, 28 had intravenous pyelography immediately after commencement of the pain. In all cases more or communications of the paint in an ease more of and the duration of the stasis varied from a to 6 and the duration of the stans varied from a to o hours. When the pairs disappeared, the stank dis nours. Other causes of stasis, such as cal

culi ureteral rupture, gravidity adjacent tumon or cuis ureteras rupture, gravatity anjacent tumon or abscesses, and allergic reactions would have been ruled out by the preliminary intravenous urography The most probable cause of stars is the formation The most processe cause of stars in the formation of blood clots which for a time obstruct the unitr

after ureteral catheterization. DAYTO RODOSTICOM 11 D

Prince, C. L.: Lumber Ursterollthotomy; The Foley Operation. J Ural., Balt., 1945 54 168.

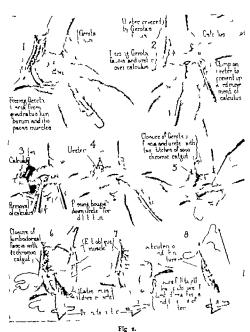

The intention of Prince is to bring to the attention and intention of Prince is to oring to the attention of the surgical profession the simple operation of on the subgress profession the subpse operation or lumbar ureternlithotomy which was introduced in 1935 by F. E. B. Foley

The author believes that 1935 by r L. B roley the author believes that this simple procedure with no cutting of muscles, this sumple procedure with no cutting of musics, without freeing of the ureter with ease of exposure, without freeing of the uterer with case of expanse, and with rapid convalescence has been neglected by the profession

Details of the operative technique including excellent illustrations by Didusch are given (Figs 1 and a) Briefly exposure of the ureter in its upper third consists of making a short (7 or 8 cm ) incision parallel to the twelfth rib with the midpoint of the incision at the end of the twelfth rib and at a distance below the rib equal to the distance of the ureteral stone below the twelfth rib as determined with x rays Dissection is carried downward to the lumbodorsal iascia by bluntly separating the latissimus dorsi nosteriorly and the external and internal oblique antenorly, and atripping these muscles from the lum bodorsal fascia below The lumbodorsal fascia is then opened in the direction of its fibers and the fascia of Gerota stripped from its under surface The posterior layer of Gerota's fascia is separated bluntly from the quadratus lumborum and psoas muscles down to the vertebral bodies. At this point the ureter can be seen and opened the stone removed exploration made with bougies closure is easily accomplished. It consists of suture of the muscularis and penureteral tissues with interrupted fine catgut and then suture of the lumbodorsal fascus subcutaneous tissue and skin. A Penrose drain is placed for 2 or 3 days. The muscles do not require suturing

Convalencemen in these cases has been smooth There has been no shock or mortality. The average hospital stay following the Foley operation in 14 cases reported by the author was 7 days. During the usual muscle splitting and cutting procedure for stones in the upper third of the ureter the average hospital stay in 14 comparable cases was 18.4 days. William W Scort M D.

#### BLADDER, URETHRA, AND PENIS

Ballesteros, M t Cystometry (La cistometria) Rev and 1943 3 200

After a brief historical review of cystometry and a short description of the anatomic, pathological, and physiological conditions of the bladder the author describes various models of apparatus used for cystometric measurements and the technique of cystometry.

Cystometry is of great importance for the discovery of disturbances of the bladder function of neurogenic type or those caused by a reflex from adjoining organs. The method is particularly valu able in cases in which locomotor stars is combined

with hypertrophy of the prostatic gland The average figures obtained by the author differ somewhat from those published by North American workers. According to the author's investigation the pressure curve indicated a normal capacity of the bladder of from 150 to 300 c.c. The maximal voluntary pressure in normal individuals ranges from 32 to 52 mgm, of mercury. In hypertonic in dividuals the capacity of the bladder is below 100 c.c. and the maximal voluntary pressure exceeds 62 mem. of mercury while in hypotonic individuals the bladder capacity exceeds 300 c.c. and the maximal coluntary pressure remains below 32 mgm. of mer cury In normal individuals the curve ascends gradually while in hypertonic individuals it rises rapidly and in hypotonic patients it is low. The maximal physiological capacity of the bladder ranges from 200 to 700 c.c. Among cystometrographs, the one devised by Lloyd G Lewis is the most precise instrument the electrocystometrograph of Landes and Vorus is also a dependable apparatus.

Sphincterometric measurements are also of great importance as they supplement cystometric studies. The most complete cystometric apparatus is the

so-called microcystometer devised by Irving Simons. The author discusses various sources of error such as infection of the bladder excessive rapidity of the injection of the fluid, rectocele, explosede and diverticula of the bladder which may produce a hypotony of the detrusor muscle stones in the bladder and tumors or infectious processes which may produce hypertonia. Josan K. NAMI M D

Leifer W., Martin S. P., and Kirby W M M t The Treatment of Gonococcal Urethritis with Single Injections of Penkillin Beeswax Peanut Oil Mixtures \ Englad J M 945 833 583

The procedure and materials used for the treat ment of genomecal urethritis were essentially the same as those described by Romansky and Ritman in 1944 (Science 100 100). The visicid preparation —even when heated in an incubator or in a water bath at 37 C for 30 minutes—was withdrawn into a syringe by a 15 gauge needle and then injected into the buttock through a 10-gauge needle. The site of injection was not massaged. No local or systemle

manifestations of toxicity of any algalificance were botted. In most cases pain and tenderness were present at the site of injection for from at to 43 hours, but these were no more severe than when benticilly in saline solution is used.

In every patient treated in this series clinical improvement was noted initially dysoria subsided during the first six or eight hours and the portical discharge became mucoid and watery. By the end of the second day almost every patient was fire of symptoms and the urethral discharge had ceased.

symptoms and the utertural discharge had ceased.
One hundred and ninety two patients of the fost of any whom the authors treated by this method could be followed up for as days and only thee were considered in evaluating the results. In as of these treatment resulted in failure boxerer there was a clinical recurrence with the return of arthrib discharge, from which gonooced were cultured in only to in the other 1st the gonooccus was detected by bacteriological methods alone. All of the 2s patients in whom treatment was considered a failure were eventually cured by further penicillin-beens as

doses of penicillin in salio's solution.

In reviewing these results, no noteworthy effects due to the character of the excipient used, e.g. the percentage of becawax used, or the sait of penkillin employed (calcium or sodium) were noted, nor did the race of the pattent (engro or while) make any difference, although the white pattents were foosd difference, although the white pattents were foosd to be alightly more refractory. Of the total 101 is the tastein who were followed up for 31 days, 85 were treated with 100 coo units of penkillin, and of these results of these 35 (1975) were cured. The remaining 13 patients were given 200,000 units and of these it were cured bowere the last group was too

small to be significant
From these results the authors conclude that a
single intramuscular injection of r o.c. of a minum
containing 200,000 units of penicillin in 4 to 6 per
cent becswar by volume in peasut oil appears to be
a highly satisfactory method of treating acros poscoreal unrefulits. Force W Brassman, M.D.

Costro E. P (Epithelioms of the Ursthra; Navicular Fosss (Epitelioms de uretra foss savicular) And, crion ared, 945 440.

The author collected 28 cases of epithelioms of the urethra from the literature and reports a case of his own in a man, aged 48 years, who had noticed an largement of the glans 8 months prior to the admission to the hospital. Simultaneously a henor thagic secretion began dripping from the nexts. Gradually burning pains developed and were responsible for impotence because they were laterium with recruitors.

There was a very marked phimosis. Palpation showed the glans to be transformed into a globular hard mass, painful to the touch. The local troupers ture was increased. A sanguincous secretion was escaping from the urethra. A catheter could not

be introduced because it was encountering a mass fust behind the meatus. The testes and epididymes were normal and no enlarged inguinal glands could be paloated. The Wassermann reaction was neva

A biopsy was performed and the examination of the piece removed from the endourethral mass established the diagnosis of a spinocellular epithelioma

An operation was performed under low spinal anesthesis. The involved portion of the penis was removed. An inspection of the specimen showed the entire navicular fossa to be occupied by a cauli flowerlike neoplasm.

Histological examination showed a malignant neoplasm connisting of the squamous type of epithelial cells which were penetrating the skin and forming numerous ramifications and anastomoses. The stroma was relatively scant. A hyaline degeneration of the epithelium was noticed in many places and there was evidence of a chronic inflammatory reaction in the stroma in the form of an infiltration with plasma cells, lymphocytes, and a few polynuclear cells. Mitoses were relatively few

Urethral epithelioma usually causes severe pain which interferes with micturation and sexual power The frequency of urination may be increased or a complete retention may develop. The latter may drappear when necrosis of the tumor re-establishes iree passage. As a rule symptoms of penurethritis accompany the induration. In doubtful cases a urethroscopic examination may be required. Biopsy allows the differentiation of an epithelioma from adenomafibroma, fibroma, or fibromyoma while serological examinations exclude syphilitic lesions. Inguinal adenopathies are relatively frequent

Chronic inflammatory strictures, fistules, and leucoplakia are considered as predisposing factors. In 60 per cent of the cases the tumor has been found in the perineal portion of the urethra.

The tumor may be either nodular or infiltrating Both types show a considerable peripheral growth. Necrosis of the tumor tissue may lead to the for mation of perturethral abscesses.

Metastases are found in the inguinal epigastric

and mesenteric regions.

Cylindrical cell formations or adenocarcinomas de riving from Littre s glands are rare and in the ma ority of cases a squamous-cell tumor is found. This is due to the frequent metaplasia of cylindrical urethral epithelium

The therapeutic method of choice is an amputa tion of the penis if the epithelioms is located in the anterior urethra. Involved inguinal glands should be removed. A removal of the testes is superfluous because they have an entirely independent lym-Phatic circulation

The prognosis is much worse if the epithelioms involves the posterior urethra while chances of cure are reasonably good if the tumor is confined to the anterior portion.

An early diagnosis is essential

JOSEPH K NARAT M.D.

#### GENITAL ORGANS

Boyd, H. L. The Use of Thrombin (Topical) in the Control of Bleeding Associated with Prostatic Surgery J Urol Balt. 1945 54 385

Boyd suggests the topical use of thrombin for the control of bleeding during and following perineal prostatectomy in the cases in which bleeding cannot be controlled by ligation of the bleeding points and the supplementary use of the Davis bag and gauge packing In his introductory remarks Boyd reviews the previous successful use of thrombin by O Conner. in cases of excessive hemorrhage following transurethral electroresection and suprapuble prostatee tomy

In 12 cases of excessive bleeding following perineal prostatectomy in which control by ordinary means proved impossible thrombin was used. The tech nique is given in detail and consists briefly of the application of a gauze sponge (z inches long) soaked in thrombin solution (5 000 units in 10 cc. of normal saline solution) to the bleeding areas within the prostatic capsule the sponge being brought out of the wound beside the Davis bag

In 1 case in which the Davis bag became partfally deflated and passed into the prostatic bed profuse bleeding was controlled by clamping the Davis bag introducing the thrombin solution through the urethra, clamping the urethra and permitting no irrigation and no catheter drainage for a period of a hours.

In I case excessive bleeding was controlled with thrombin introduced and localized to the prostatic space by means of the Trattner partition catheter

WILLIAM W SCOTT M.D.

Millin T : Retropuble Prostatectomy; a New Ex travesical Technique Lancet Lond. 1945 249

The outstanding features of retropubic prostated 1 It is an extravesical procedure by which supra

pubic bladder drainage with its risk of alow closing or persistent fistula is avoided.

2 It is applicable to all types of prostatic obstruc

3 It is relatively short and shock free.

4 It appears to be anatomically sound no important organs being interfered with or endangered. 5 The mortality is singularly low No deaths

have occurred in the first 20 cases. 6 The postoperative course is easy for the patient

and attendant staff 7 The whole of the obstructing tissue is removed

so the risk of recurrent obstruction is obviated

8 The postoperative stay in the hospital seldom exceeds a weeks.

Preoperative treatment When the signs or symptoms suggest the necessity or desirability of oper ative intervention the usual preliminary tests of renal and cardiovascular functions are made. Par ticular emphasis is laid on preliminary intravenous

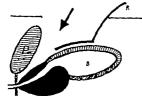

Fig. z. Retropuble approach to the prostate: P pubis, B bladder: R, retractor

urography From this study is ascertained evidence of ureteric dilatation, unexpected gross hydrone phrosis, vesical diverticulum, urinary calculi, and approximate residual urine without the necessity of urethral instrumentation. When actual retention has supervened suprapulse puncture is being treed initially with a small hydrocele trocar and cannula, and repeated when necessary until renal function studies have been made. When the initial puncture reveals infected urine, a No. 8 rubber Themann extheter is passed per urethram and retained in sits When the urine is uninfected and renal function adequate urethral instrumentation is not used be fore the patient is on the operating table.

Operative technique. The patient having been anesthetized either by low spinal anesthesia, with pentothal, or with pentothal and gas-oxygen, as indicated a rapid cystourethroscopic examination is made to rule out unexpected bladder pathology and to study the exact configuration of the gland The bladder is emptiod, and while the surgeon is changing his gloves and gown, the assistant prepares the operative field, i.e. the lower abdomen and penns. The penis is covered with a loose sterile towel. A midline incision is made starting over the publs and extending upward 11/2 or 3 inches, accord ing to the obesity of the patient. This is deepened in the usual manner and the aponeurosis is incised in the whole length of the wound Bleeding points are caught in bemostats and congulated with the disthermy needle. The recti are then separated in the midline and the index finger inserted at the lower extremity sweeps the retropubic fat and peritoneal fold upward. A modified Harris self retaining retractor is then introduced. The lateral blades keep the recti widely separated and the posterior blade

preses the bladder operard and backward (Fig. 1).
A flexible lamp resting on the publis is dipped into
the retropublic space thus opened up and the distribution of the veins coursing upward on the anterior and lateral supects of the prostate is noted, asthis appears to wary considerably. The veins are
situated in the preveitful layer of the endopevic
fuscia. The central lessh arising from the deep
dorsal vein of the pens is underrun with the boom-

erang needle and ligated. The group on each side is similarly treated. The fat still athermit to the lateral supects of the gland is gently supped downward and outward, any velus inadvertenily tora is this process being promptly seized with hemostate and subjected to disthermy. The anterior and alteral surfaces of the gland being cleared in this way a medium sized swab is pushed into each lateral recess.

With a diathermy knife or No. 15 Bard Parker knife a curved transverse incision, convex downward, 1 cm distal to the bladder neck, is made through the pre vesical fascia and true prostatic capsule. Suction is maintained to keep the field dry and to enable the operator to grasp any bleeding vessels in the distal lip with curved kocher forceps. With these forceps used as tractors the lower flap is undermined toward the apex of the gland with Device's long disserting scissors. The Kocher forceps are removed after being touched with the disthermy needle. The upper flap retracts because of the pull of the severed pubovesical muscles. The anterior and much of the lateral aspects of the false capsule now being ex posed an inverted V incluon is carried down to the adenoma, which is readily recognized by its typical whitish appearance. The \ shaped flap is elevated which opens up a lozenge shaped space. With the doord curved dissecting scissors the lower margins of the lateral lobes are freed from the false capacie. The dissection may be continued with the scissors, or, as the author prefers, with the finger For this purpose it is best to remove the retractor temporarily. The lateral lobes and when present, the middle lobe, are freed digitally from below upward until they present in the wound, being attached solely in the region of the bladder neck. The pedicle is seized on each side with Kocher forceps and the adenomators man is detached with scissors or the disthermy needle. The forceps are touched with the disthermy needle and removed. In 1 instance only has a steadying firger

in the rectum been necessary. The retractor is now replaced the field swibed and sucked dry and the edges of the false capsals are secured with a pairs of Alis Jorceps. By traction on these and suitable manipulation of the fernile lamp and sucker the prostatic bed is carefully inspected. The two prostatic settines, if not shready secured in the pedicle, are easily seen bleeding close to the bladder neck at 5 and 7 o chock. They are selected with hemostars and coagnitized Any other obvious bleeding vessels are similarly treated. This are present on the contract of the

Bleeding having been controlled, the towel correing the penis is then raised and a No. 18 Harris catheter passed along the urethra into the protection of the penish and thence guided into the bladder With the assistant steadying the Allis forces on the margins of the false capsule, the operator closes the defect with a continuous source of No. o catert, using the boomerang needle. The transverse facision

in the true capsule is then approximated over this with a or more interrupted No o catgut sutures All obvious bleeding should now have been controlled The lateral recess packs are removed the field is cently swabbed dry of clot and sprayed with sulfanilamide powder and a small corrugated drain is placed down to the suture line. The self retaining retractor is removed and the rectus sheath closed with interrupted No. 2 catgut sutures. The skin is closed with allkworm gut Bilateral vasectomy is then performed. The catheter is next prigated with 1/5000 flavine to free it from any clot it may have collected during its passage through the prostatic bed. Four ounces of fluid are left in the bladder and the eatheter is spigoted. Two silkworm sutures fix the eatheter to the skin of the penns A 4 foot length of sterile tubing with a glass connection of even bore is then attached to the catheter, the lower end of the tubing being spigoted. The operation time need not exceed half an hour and is often nearer 20 minutes.

IOHN A. LORE M.D

#### MISCELLANEOUS

Cordonnier J J: Vesicoureteral Reflux Accompanied by Renal Colic. J Am M Ass., 1945

The role of vericoureteral reflux in the production of renal cohe was brought to our attention by Lewis and Caroll in 1934 all cases described by them were secondary to vesical neck or urethral obstruction, and the typical renal colic occurred in the presence of a distended bladder when the patient attempted to void.

Diagnosis is established by filling the bladder with an opaque solution, taking an x ray film, having the patient void, and then taking a second film

The etiological factors are (1) mechanical obstruction of the vesual neck with upward dilatation and alterations of the uncteral orifice due to chemcal, inflammatory and postoperative changes (2) patent untersal orifices associated with nerve knows as in cauda equina lesions and (3) congenital untithal valves

Two cases with typical renal colic caused by

rescoureteral reflux are presented

I caicountieral reflux should be suspected in cases of read codic, particularly if no stone in demonstrable and venual neck obstruction is present. Postopers the untercoversical valve cleatrices may be followed by vestoounteral reflux. A routine cystogram alone may cause a reflux to be overlooked, and a second film, taken after the patient has voided should be taken.

DAWD ROUSENDOOM M.D.

Marshall C. J : Tubercle Bacilluris. Bril J. Urd., 1945, 17 tos

While a series of II cases is much too small for statistical analyses it may however bring out a few points of particular interest.

The presenting symptoms of these cases of tuber de bacillura were the classic triad found in urinary tuberculosis but in addition the importance of the node in the epididymus was fully borne out. Whether every case of chronic epididymus is should be subjected to full urinary investigation remains for discussion it would seem however that there is one unequivocal indication—the examination of the twenty-four hour specumen for cells and bacilli. This simple but nevertheless searching test should never be omitted. Open tuberculosis cannot fail to make itself evident at least by the presence of leucocytes, if not of bacilli, the presence of either or both, of course, calls for the full reentgenographic investiga too, with cystoscopy.

There remains the case of closed tuberculosis in which cells are not found in the twenty-four hour specimen such cases must be uncommon but never theless they are on record. Such cases will be mused unless excretory roentgenography at least is per formed.

The overwhelmingly important question however is that of treatment. In view of the evidence that small lesions do heal, even with calcification, it seems that there is strong justification for a policy of conservatam. Unnary tuberculosis is not a ful minating conduition on the whole it is only slowly progressive and further vesical lesions, in general, present a high degree of recovery once the renal disease is removed. The progress of the condition lends uself to very precise observation again, repeated examinations of the twenty four hour specimen provide clear indications for repetition of the cystoscopic and reentgenographic investigations

Therefore it seems that if conditions in general are favorable and the patient is co-operative in the mat ter, so-called expectant treatment is permissible. Only one further point is to be emphasized that is, how permanent is the healing of renal tuberculous? It will be noted that even in this small series there were cases in which healing occurred only to break down later on, and it was common experience in nephrectomy for gross tuberculous to find areas of calcification indicating healing in the remote past, with recurrence of extensive destruction. It may nevertheless still be argued that in view of these considerations-ease of control and slowness of prog ress-the tendency to later breakdown still does not invalidate the soundness of the conservative attitude m simple bacilluria. There was little support for it in the cases presented Gross tuberculosis was found in each one submitted to nephrectomy and in 3 the old healing had broken down again of the conser vatively treated cases 1 developed gross renal tuber culosis and in the others tubercle bacilli were still present in the urine.

JOHN A. LOUT M.D.

Ward, R. O : Some Surgical Aspects of Urinary Bilharziasis. Prec R. Soc M Lond. 1945 39 27

Bilharsiasis is a disease which produces many important changes in the urinary tract and is if only for that reason worthy of the interest of urologists. Examination of the wrise. The most general method of making a disposis of bilharrians hema tobia is to examine the last drops of urine passed or the centrifuged deposit of the urine of the patient under a ½ inch or ½ inch objective. No staining is required The own with their terminal spines are easily recognized. In the late stages the sclerozed bladder may be palpable in an emacusted patient, and per rectum extensive induration may be found to involve the prostate and vesicles and all tissues at the bladder base and in the perform

The importance of cystoscopy in diagnosis (1) A solitary examination of the urine for ove is a quite unreliable test, for ove are not continually released from the lesions of the mucosa. (2) Five consecutive morning specimens, the last few drops of the prine being collected and centrifuged will show either ove or red blood cells in about 85 per cent of the cases the latter being strong evidence in the mass examination of natives that bilharria is present. (3) Even in the absence of ova or red blood cells the continual presence of pus or albumin in a native s urine means that a diagnosis of bilharma is probable until it has been disproved. (4) Cystoscopy is the most accurate method of diagnosis in all active phases of bilharmasis. Moreover there are several characteristic vesical changes which pensist when the active stages of the disease are past. It may be argued that cystoscopy does not reveal lesions of the kidneys and the urethral mucosa that must be admitted but it is probably very rarely that these timues are affected without vesical involvement.

Cytloscopic oppearances in remail billioristaris. The earliest abnormality seen in the bladder mu coas is the appearance of patches of congestion which occur most commonly in the trigonal region these, however have no characteristics which enable a certain diagnosis to be made. Subsequent stages are specific.

The first of these stages is very typical. Bilharrial tubercles make their appearance. Each of these is about as large us the tubercle due to Koch a bacillus (to which it bears some resemblance) that is to say about the size of a pin a head. It is raised above the level of the mucosa and is surrounded by a narrow ring of congested vessels. It has a shining surface and a faintly yellow color As it grows and dies the shine diminishes, and the yellow color remains and is sometimes intensified while the surrounding hyperemia becomes less or may disappear entirely The bladder mucosa which lies around a collection of these tubercles is sometimes congested but it may be very little different from the normal. When an intense invasion by ova is in progress very marked bullous edema is often produced. It is difficult to say how much of this is a mere reaction to the ova and their toxins, and how much of it is due to venous blockage by the worms, but probably the former is

the more important cause.

Calcification of the bladder tissues around the ova is a prominent feature in all severely infected long standing and untreated cases.

One local result of calcification is what is called sandy patches in the mucosa.

The process of calcification afferts chiefly the submuccorn layer of the bladder wall. It is by no mean necessarily accompanied by secondary infection, and on cystoscopy in such cases the bladder has often been clean. When this was the case it was usually very pale because of scierosis and diminustion of the vessets. This calcification forms a barrier in which many ova perish and through which others cannot work their way.

Another stage is the divisionment of a billurial uker. This may be clean and without dough, if it usually single and Maker says that he has never seen this type of their become malignant. More often secondary infection is coexistent, and in such cases an uker also usually a solitary one, has a slouthing hase and marked cystifts is present.

Vesical papillomas due to bilharria are common in This is a true neoplastic condition and Egypt frequently malignant. In that country cancer of other organs is uncommon, and these growths are considered to be the result of the toxins of the ova. A bilharxial papilloma unlike a granulomatous mass with which it sometimes may be confined by of course, not to be cured by medical treatment. These growths do not have long fronds but are of firm consistency Usually there are only 2 or 3 of them. The commonest variety of bilhardal papilloms met with in Egypt is of bulbar form and dark red color although in parts it has a grayish white appearance due to septic necrosis and to phosphatic deposits in the growth. These growths may spread and in rare cases involve the greater part of the bladder Nodular infiltrating carcinomas are less common. In the series of 130 cases, 10 were of this variety. This variety has the characteristics with which we are familiar and follows the course com mon to all bladder carcinomas of this type.

In untreated cases the musculature of the bladder which is the seat of this disease, tends to be thick ened partly because of hypertrophy and partly because of fibrosis due to the additional development of prostatic and urethral obstruction, remiting from bilharzial changes in those tissues. Despite such obstruction the bladder in these cases often remains contracted and this renders suprapuble cystotomy very difficult or impossible. Urinary fistulas which are a direct result of the disease produce the same result. They affect all parts, but particularly the floor of the urethral bulb and are often so numerous and extensive that when the male patient squats to micturate the perincal effect resembles the spraying from the rose of a watering can. These fistules sometimes track widely

Vesical calculi are met with in bihardissis and in rare cases the owa have been found within the stone. These calculi appear to be composed of unic acid and oxalates, and are formed upon definis. Prosphatic calculi are very common when sepais has become severe. Renal calculi are also encountered, although they are very much less frequent.

Ureteral obstruction of moderate degree is often encountered during the active stage of the disease In such cases it will disappear when a course of treatment with antimony has had time to kill the worms and thus cause the acute reactive processes to resolve

Chronic areteral stricture is a very important and frequently insidious result of bilharziasis which we must be prepared to diagnose and to treat affects the lower parts of the duct for the upper portions lie in an area which is but rarely invaded by the worms. Most of the various pathological conditions which arise in the vesical mucosa may also be encountered in the ureters, but stenosis is the common complication Although it may sink into relative insignificance in the clinical picture of a native affected by advanced urinary bilharmasis, yet in such patients death from infected bilateral hydronephrosis is common. These strictures how ever are encountered in patients who appear at first sight to have recovered completely from the

Dilatation of an established stricture of the weter is best effected through an instrument of the McCarthy panendoscope type with some form of still ureteral dilator. Such a method when possible is very effective more so it seems than in any other types of preteral strictures and although the case requires further supervision the cure is often complete.

The author does not discuss the general treatment of urinary bilharziasis or of the later complications of the disease.

Tartar emetic remains the best drug for treat ment, despite some unpleasant effects experienced by the patient during the period of administration. The course should amount to a total of 30 gr and it must be intensive lest the parasites acquire a resistance to antimony There are also some more recent prep arations such as stibophenum anthiomaline and louadin. These are administered intramuscularly this is of great value in the treatment of the school children of the Delta. These preparations obviously have advantages when large numbers of troops are treated but they are not considered to be so cer tainly curative as is antimony sodium tartrate Antimony first sterilizes the generative apparatus of the female worms and ultimately destroys them It is not known just how certain is the effect upon those ova which have been deposited before treatment was begun.

It will be agreed that we must keep our eyes open for occasional cases of this disease. Not only officers but men of all three Services have been in the countries where this disease is endemic.

TORN A. LOXY M D

Combes, F C. Canizares, O and Landy, 8.: Lymphogranuloma Veneroum. Am J Syst.,

The problem of diagnosis of so-called latent forms of lymphogranuloms venereum has never been solved and this inability to determine the presence or absence, or the degree of activity of the disease is a serious handicap Patients considered cured discharged, and allowed to resume their normal activities frequently have a residual, small hard mass in the inguinal region which has been interpreted as a fibrotic reaction and a sequela of the reparative process but there is no proof at present that these patients are definitely cured and that they do not harbor dormant but viable virus in these nodes. The same problem exists in patients with anogenitorectal involvement. A test capable of detecting evidence of activity during these latent" periods should be invaluable. The Frei reaction persists after con valescence for an indefinite time, and is not an indi cation of the degree of activity. The complement fixation test of Grace Shaffer and Rake is not yet standardized and perfected

There are definite changes in the blood serum proteins of patients with lymphogranuloms venereum, chief of which is a hyperglobulinemia. The formol gel test is predicated upon the presence of an increase in seroglobulins, and is not specific for any disease A rapidly positive formol-gel test indicates a high seroglobulin The authors made formol-gel tests and albumin-globulin ratio determinations on 42 cases of lymphogranuloms venereum and formol-gel tests on 307 controls. Of the 42 known cases of lymphogranuloms venereum, 38 had positive formol-gel reactions after the disease had been present for three weeks and these were consistently positive after the disease had been present for several months or years especially in active anorectal cases. Of the 307 controls only 6 gave positive reactions. The authors conclude that the formol-gel test is a simple reliable bedside procedure of value to determine the presence of hyperglobulinemia in lymphogranuloma venereum There was a tendency toward a return to normal after a clinical cure in 85 per cent of the cases. Hyperglobulinemia is of some value in determining the degree of activity of lymphogranuloms vener eum and formol-gel reactions and albumin globulin ratios should be determined in all patients as an aid in treatment and for indication of biological cure DAVID ROSENBLOOM M.D.

Magnuson, H J., and Eagle, H.: The Retardation and Suppression of Experimental Early Syph Ills by Small Doses of Penicillin Comparable to Those Used in the Treatment of Gonorrhea.

Am J Syph. 1945 29 587

The widespread use of penicillin in the treatment of gonorrhea has raised several problems with respect to the effect of such therapy on concomitantly ac quired syphilis. Since the doses of penicillin usually employed (100,000 to 200 000 units) are sufficient to cause the disappearance of treponema pullidum from primary lesions which were previously dark field positive and since these doses are subcurative for established syphilis in man it is conceivable that such therapy given during the incubation period of syphilis might (a) prolong the incubation period

(b) suppress the symptoms and result in an asymptomatic infection, or (c) actually abort the syphilis A number of cases have been reported in which peal cillis therapy for gonorines has rendered the dilag nosts of syphilis difficult either by making a presisting but unrecognized primary lesion darkheld negative or by delaying the appearance of symptomatic or serologic cridence of the disease.

The authors demonstrated that, in rabbits amell doses of penicillin have definite suppressive effects on the development of the lesions of early syphilis. The smaller the spirochetal inoculum the more pronounced is the suppressive action of penicillin and the suppressive action is maximal when the penicillin is given before the seventh day of the illness When penicillin falls to prevent the appearance of the primary lesion, it regularly causes a algoificant prolongation of the incubation period probably because most of the organisms have been killed by the penicillin and the few residual organisms take more time to develop a primary lesion. In some cases the primary lesion and the infection were aborted In general, the smaller the inoculum and the earlier treatment was begun the greater was the proportion of inoculated sites at which lesions failed to develop

Clinically doses of penseilin comparable to those used in the treatment of gonorrhes may materially modify the course of syphilia simultaneously acquired in many of the cases the incubation period is merely prolonged and the patient may no longer be under medical supervision at the time of development of the lesion. Patients treated for gonorrhes with peniellin should be followed up both clinically and seriologically for a minimum period of 4 months after exposure in order to minimize the possibility of delayed primary lesions or clinically "asymptomatic syphilitic infections, and the patients should be specifically advised of this danger.

Joshi, L. B.: Urinary Calcult Ind J Surg 1945

The author's article may be summarized as follows

i The uriniferous tubule probably acts on the

- principle of a flush.

  a All deposits in the kidney which are insoluble plaments, and casts could be seeds of urinary stones.

  3 Sodium chlorides and sulfates have the
  - property of preventing the formation of urinary stones.

    4. The tertiary rock map of the world in associa thon with the big rivers resembles the map of distri-
- button of urnary stones.

  The scarcity or abundance of water has no
- of the scarcity of abundance of water has no effect on the incidence of urinary stones.

  6. The temporary hardness of water is one of the
- most important causes of urinary stones
  7 The envelope shaped crystals seen in oxaluria
  are composed of potassium oxalate and not of cal
  cium oxalate.

- In cases of phosphaturia, gaatric analysis often reveals achlorhydria or hypochlorhydria.
   Calcium sulfate is a fairly common con-
- atituent of urinary stones.

  10. The age incidence of urinary stones probably
- depends on the general standard of health and care of children.

  11 Town people acquire more urinary stores
- (than the rural population) if the water is not chlorinated or filtered.
- 12 Whales sailors of old days, and long term jail inmates have no urinary stones

JOHN A. LOEP M.D.

Wilson, J. G. Benjamin, J. A. and Leaby, A. D.: Study of Experimental Urinary Calculi, Methods for Producing and Preventing Calculom Formation in the Bladder and Uratina of Albho Ratt. J. Ural. Ralt., 1945, 34 59.
Newborn albino rats were injected thrice weekly

with 0 : magm, of estradiol diproporionate for a period from a to A, weeks as that the total desage was either 0 6 or x s mgm. Seventy-eight injected admais were fed on a commercially prepared stock ration which did not vary much from other such preparations, all of which are of a high maneral content. Thirty-four animals were fed on a low mineral duct which was of smiticent amount to be compatible with normal growth and reproduction. Beginning at yo days of age periodic examinations by palpation of the bladder and the urethra, and by x ray were made to detect the presence of stocs. Urinary infection was ascertained by culture and by the ability of the organisms to split tera. The urine

9.11 was determined on each specimen. Forty five animals were fed on a high raisent diet until the presence of stones was ascertained, death ensued, or until 7.5 months of age was reached. In this group there were 30 male animals, 24 (83.6%) of which developed vertical or urether clearly between the first and the different months, and during this period zone of the females or control animals depended zone of the females or control animals de-

veloped stones. In order to determine the accuracy of x ray and palpation as a method of demonstrating unnary calcult 23 male and 12 female animals were fed high mineral diets after wearing and were sacrificed at intervals for autopsy. The results confirmed the opinion that the stones began to form somer than they could be detected by means other than antopay The authors state that if all the males had been per mitted to live to the age of 110 days, it may be estimated that at least 10 (47 6%) would have yielded stones at autopsy as contrasted with so. per cent of known cases of lithiasis at this age in the previous group of male animals. Also I female in the autopsied series was found to have stones in the bladder There was no difference in the incidence of stones in the group receiving 0,6 or 1 2 mgm. of

estradiol diprogionate.

Cultures of bladder urine of injected males
showed infection whether or not calcull had formed.

Specimens from 13 older maies yielded escherichia coll in 10 and the remaining 3 showed a nonhemolytic streptococcus alpha hemolytic streptococcus and a mixed streptococcus feeding and contraction existed between the infectious agent and the age at which the host formed calculated the remaining of the same showing calculi was always more or less alkaline. Urmary infection always preceded calculus formation

Seventeen of the 24 males with infection showed focal attes of infection in the bulbourethred gland and occasionally in the prostate seminal vesicles or bladder wall but rarely in the kidney. In the injected females 9 of the 20 had infected bladder urne, but it is of particular interest that at necropsy not a angle matance of local infection was found in the urnary tract. Focal infections were observed in the attophen uteri and oviducts in 8 of 28 cases but were not always associated with infection in the urine.

All stone bearing males revealed some unnary tract abnormality with a variable resultant stass. The most perastent finding was obstruction between the bladder and urethral sinus which seemed occasioned by the common finding of an abscessed bulbourethral gland. Then too the sectioned bulbourethral gland. Then too the sectioned urethra at this point of several young estrogen injected rats revealed great numbers of desquamated comified cells, often in the form of large plaques suspended in the lumen. No urinary obstruction was found in the female animals except in the one which developed a stone

Nineteen males and 15 females were injected during the first a weeks of life. They were fed a low mineral diet and secrificed after a period of 180 days. Two males in this group revealed calculi the other animals were free of atones. The atone incidence in this group was reduced from 81.8 per cent to 10 5 per cent by feeding a group of injected animals on a low mineral diet.

The authors concluded from their experimental work, that (i) infection preceded stone formation (c) alkalunura was characteristic of stone forming animals (3) neither the type of organism nor its urea splitting potentialities was related to the urine H or calculus formation (4) urinary stasis accompanied calculus formation but was not necessarily responsible, and (5) lithiasis so produced could be materially reduced by a diminished mineral dict.

ROSERT LEM, JE., M.D.

Benjamin J. A. Wilson J. G., and Leahy A. D.: Study of Experimental Urinary Calculi; Quantitative Microchemical Spectrographic, and Citric Acid Analyses of Albino Rat Calculi, with a Preliminary Apatite Report. J. Ural. Balt., 1015 62, 516.

The stones analyzed in this paper were produced experimentally in rats by feeding them on a high mineral diet and subjecting them simultaneously to injections of estradiol dipropionate. The calcult varied in size from x to 6 mm.

Ninety per cent of the stones showed a composition of magnesium ammonla, phosphate, and moisture Calcium was found in small amounts as was citrate and carbonate in only minute amounts. These results were confirmed by spectrographic analyses. It was found that carbonate-apatite was a common constituent of the stones studied

The principal chemical constituents in this series of calculi were reasonably constant, tirrespective of the size shape, or site of origin. Bladder calculi as compared to urethral calculi were white in color rather than brown but in both, magnesium am monium phosphate hexahydrate was the principal compound, though the urethral calculi contained calculm and more phosphate.

Spectrographic studies confirmed the findings, and occasionally revealed small amounts of sodium iron aluminum and allicon Rosert Lich Ja M.D.

# SURGERY OF THE BONES, JOINTS, MUSCLES, TENDONS

CONDITIONS OF THE BONES, JOINTS, MUSCLES, TENDONS, ETC.

Jönsson, G i Haa Acute Hematogenous Osteomyslitis Become Less Common and Less Severs? Acts chir send 1945 92 533.

The author has gone through the material of 30 years (1913-1941) of hematogenous exteomycilitis seen at the Surgical Clinic in Lund. This followed a suggestion made during the last decade that acute hematogenous osteomyelius has changed in character in that it has become less severe with the years and at the same time a disease that occurs less and less frequently

The material consists of 135 cases. Its distribution regarding sex and age corresponds to the figure usually given. If the cases are divided into 5 year periods one finds that the smallest number has been treated during the last period during which no death occurred. The study reveals that a smaller number of complications have occurred during the last 5 year period as compared with entire ones. The duration of treatment has been considerably shorter during later years. During recent years the patients condition on admittance to the clinic has been much better than formerly. In ocarly all of the cases the treatment has been operative. Serum or chemotherapy has not been employed in any of the cases.

The Lund material gives one the very definite impression that the disease has had a considerably more benign course during later years than previously, with fewer deaths during the septic initial stage fewer complications during the later stages,

and a more rapid course of healing

Buchman, J., and Biair J E.: Penkellin in the Treatment of Chronic Outcompelitie. A Preliminary Report. Arch Surg. 1945. 5

The authors conducted a clinical and becternlog ical study of the results of treatment of chronic ostcomyellus with penicilin, with and without surgical intervention. There were 68 lesions in 47 natients.

Some of the conclusions drawn are tentative be cause of an insufficient period of follow-up but others are sufficiently clear and certain

The use of penicillin alone, whether given by local application or intramuscular infection, is totally in effective in chronic outcomyclitis. If after preoperative and postoperative administration of penicillin and thorough saucertration the resultant wound is allowed to beat by granulatoo the results are not materially inducenced by the addition of penicillin to the treatment. The same type of treatment and delayed primary closure (rather than allowing heating by granulation) constitute a considerable improvement over previous methods. The treatment of chronic acteomyclitis by preoperative and post of chronic acteomyclitis by preoperative and post

operative administration of penicillin, thorough saucerization of the focus of infection and pumary closure of the resultant wound gave entraonlinearly good results in 23 of 27 patients, but the arthon state that the postoperative period of observation was insufficient

Of the tuberculous lesions of the bones and joint secondarily infected with congolose positive study lococcus surveus, treated by the properative and postoperature administration of penicillin, and subjected to thorough succertation and primary desure a limited number presented primary besling over a short period of observation

A distinct advantage of primary closure is the reduction in the incidence of secondary infection which so frequently (80%) complicates delayed closure. Staphylococci pernisting in wounds being by granulation or delayed closure develop increasing resistance to penicillin.

DOREL II LEVENTIAL M.D.

Alterneler W. A., and Reineke H. G.: Roentgenegraphic Interpretation of Acute Hermatogenous Outcompelitis Treated with Penkillin. 4st J. Reesig 945 54 437

The Introduction of penicillin has completed altered the management of acute hemotopeous osteonwebits. The rapid control of the general acol local infection makes as emergency surpeal deconpression of the area of the bone involved unaccessary countries as a rule, is functed to inclosure and drainage of abscenses of the soft theore and or moved deconpression of the soft theore and or removal discussions of the soft theorem and to removal discussions. Because of this milder course the bootenages which follow above a different appearance from that which is known to characterus the seasurement and the second of the countries of the soft the soft of the soft the soft of the soft of the soft of the soft the soft of the sof

During the past 37 months the authors observed 52 cases of acrote bematogenous estempedial treated with pendellin. In 44 of these the osternychitis was localized to the long boors, in 44 of the ethodogous agent was represented by the bemolying staphylococcus aureus in 32 cases, the nonhemolytic staphylococcus aureus in 32 cases, the nonhemolytic staphylococcus aureus in 35 cases, the hombotic streptococcus in case the pneumococcus III in 1 and 18 remained undetermined the 4 cases.

All of the cases were treated with pencilla, at though in 38 limited amount of aditionamiles are given prior to the pencilla. The early case reci ved less than Aco oco units of pencilla, but centually a total of 1 sococo units remainly venously or intramucularly at the rate of from 15,000 to 15,000 units every 3 bours proved the most desirable dosage. In some cases it was administered by intra remousl drip at the rate of from ministered by intra remousl drip at the rate of from

as to 30 drops per minute in the form of 2 000 c.c. of physiological anime solution containing 30 000 to 80,000 units of penicillin. The dose was reduced when it became apparent that the infection was controlled.

The results were remarkable. All patients recovered except 1 so that the mortality was only 1 o per cent. The period of morbidity likewise was

strikingly reduced

Clinically the cases were divided into four groups Group 1 The correct diagnosis was made within the first 2 or 3 days and adequate treatment started

immediately The results were truly excellent Group 2 The diagnosis and treatment were moderately delayed Here the infection was brought under control in 2 3 or more days and local soft tissue abscesses developed more fre

Group 3 The diagnosis and treatment were de layed for from 7 to 10 or more days when the infection was unusually severe, local destruction of bone became very great, and soft tissue abscess formation and sequestration occurred in most cases In this group the infection was arrested with more difficulty and rather prolonged treatments were necessary Small abscesses were treated by aspiration, large ones by incision and drainage and the sequestra were removed

Group 4 The esteemyelitis was so fulminating that surgical intervention still constituted an emer gency measure. In such instances penicillin at the rate of 15 000 units every 1 to 3 hours was given

preoperatively and postoperatively

The roentgen changes in the various groups were

interpreted as follows

In group r the bone alterations were minimal consisting of areas of localized periosteal reaction small areas of patchy decalcification of the under lying cortex, little or no evidence of sequestration and ultimate reconstitution of the bone. In 3 cases

the roentgen findings were entirely negative In group 2 the changes likewise were minimal at the beginning of the treatment, but after a week or

so periosteal reaction and patchy demineralization of the underlying cortex became evident. These in creased in extent and degree, becoming most marked in from 1 to 5 months after the onset of the infection Then, recalcification followed with rapid return to normal. Sequestration occurred only occasionally In group 3 there was extensive bone destruction at the start of the penicillin therapy This increased on subsequent examinations Small sequestra were absorbed spontaneously and larger ones acted as autogenous grafts. Rarely was the sequestrum discharged. Recovery followed eventually

In group 4 the bone destruction was very exten

sive due to the severity of the infection

The authors include detailed clinical histories of 6 typical cases and use serial roentgenograms to illustrate the course of the disease under the in fluence of the penicillin therapy and the good re sults obtained T LECCUTA, M.D.

Lewis R. W : Differential Diagnosis of Tuberculosis in Joints of the Extremitles. Am J Rossig 1945 54 329

In 1924 Phemister described the principal enteria of differential diagnosis between tuberculous and nontuberculous suppurative arthritis. These cri terra still stand although they are not as widely employed as their importance warrants. Therefore, the author wishes to restate them and add some new ones of his own

According to Phemister in pyogenic arthritis there is early narrowing or disappearance of the joint space because of the fact that the articular cartilage is killed and broken down first at the points of contact and pressure of the opposing articular surfaces For the same reason the earliest bone destruction occurs in the opposing or weight bearing portions of the articular surfaces. In contrast to this in tuberculous arthritis the joint space is preserved for months or years since the earliest destruction is peripheral along the surfaces where tuberculous granulations can grow Likewise the earliest bone destruction is not on the contiguous opposing bony surfaces but about the margin of the weight bearing surfaces.

To these points the author adds (1) in acute pyogenic arthritis osteoporosis about the foint is rapid and marked whereas in tuberculous it is usually lacking (2) acute pyogenic foints show a distinct tendency toward repair and ankylous features which are customarily absent in tuberculosis and (1) in tuberculosis the adjacent muscles often are markedly atrophic which is not the case in acute

nvogenic infections

Unfortunately however the picture is not always so clear. There are many variables due to difference in virulence of the invading organisms and reaction in the host. Another confusing factor is the apparent difference in the roentgen manifestations of certain joints as for example the hip joint, in which the criteria of Phemister are seldom observed and therefore the differential diagnosis must be more circumspect. Still another difficulty is created by the rather infrequent but enturely different form of tuberculous the so-called caries sicca.

The differential diagnosis of tuberculosis of loints from other diseases than acute pyogenic infection as a rule, is quite easy aithough lymphatic leucemia and probably some other conditions may simulate

tuberculous arthritis.

Several illustrative cases are presented to prove the various points. T LEUCOTIA, M.D.

Simon H E: Muscle Hernia, with Report of 6 Additional Cases in the Arm and Leg. Mil. Sur PLON 1045 97 369.

Muscle hernus or protrusion of muscle tissue through a defect in the overlying fascia is rarely recognized in civilian life. In military service, it is frequently observed and often symptomatic. The author presents 6 case reports to add to the 163 cases of muscle hernia described in the literature. Three of the patients developed the hernias in the Laire of the patients unvested the nermas in the lower extremittee and 3 in the upper. The condition somer extremutes and 3 in the upper 1 in condition occurs almost invariably in the third and fourth occurs almost invariably in the third and fourth of the state occurs samos invarianty in the title and decades and is practically limited to males.

Johnson of the Charterhouse Rheumatism Clinic in his part of the symposium pays special attention to the prognosis of spondylitis in relation to treat ment. He takes exception to the very gloom; view as expressed in Volume 2 of the British Encyclopedia of Medical Practice (1936) The books of the Char terhouse Rheumatism Clinic contain reference to some 500 spondylitis patients. A review of these records reveals an entirely different aspect.

The disease is almost certainly an infection pos sibly due to a form of tubercle, although some regard it as a disease of the endocrine system. In many instances breakdown of the natural resistance seems to be determined by physical overstrain or by an accident. In the untreated case the prognosis de pends on this breaking down of the natural resistance.

Some years before his death Scott introduced the wide field method at this institution for the x ray treatment of ankylosing spondylitis. The principle behind this method was to stimulate the natural re sistance. The results were so satisfactory that the method is being continued An average dose of 50 roentgens twice a week is given but in some cases it is reduced to 10 roentgens to avoid all possible un pleasant reaction. Hemoglobin estimation and special sedimentation tests are often necessary guides. The total dosage in 1 year is not allowed to exceed 1 500 roentgens

If x-ray treatment cannot be given stock vaccines of streptococci and staphylococci given weekly are often a good substitute Other forms of stimulus, such as cold or even ultraviolet ray baths, may be of value. Potential foci of infection should be removed

Under such care the prognosis as regards the con tinned capacity to earn a flying is good Nearly all patients of the Clinic are able to hold down ordinary lobs. Neither are they dissuaded from marriage. There is no proof that the disease is hereditary T LEUCUTIA, M.D.

Hooker D II : Brachymetopody Bull Johns Hopkins Hesp., 1945 77 329

Brachymetopody is a condition in which certain digits of the hand or foot are shorter than normal. It is caused by abnormally short metacarpals or metatarnals, respectively Three cases are presented in which there were short fourth toes.

The chief complaints were metatarsalgue, callosthe over the metatarsal heads and relaxed longi todinal arches. The condition apparently was present at birth. All of these patients began having

Fig. 1 Shortening of otherwise normal fourth metatarsal bones, each metatarnal being about 13 cm shorter than the adjacent third metatarnal.

trouble with their feet after basic training in the

A hereditary factor was established in every one of these cases. The treatment consisted of arch supports, metatarsal pads, weight reduction and lumited physical activity

A congenital origin of brachymetopody is sug gested by the author GRORGE L REIM, M.D.

### SURGERY OF THE BONES, JOINTS, MUSCLES, TENDONS, ETC.

Knight, M P., and Wood G O : Surgical Oblitera tion of Bone Cavities following Traumatic Os teomyelitis. J Bone Surg., 1945 27 547

High velocity war missiles have not only contributed many cases of osteomyelitis of the long bones but have furnished the orthopedic surgeon with many massive soft tissue and bone defects. Since skin and muscle defects over the long bones un equivocally interfere with bony repair the authors have devised a new approach for the expeditious obliteration of such cavities. It is apparent that if let alone, these defects would prolong rehabilitation and increase morbidity To expect bone growth to ensue in the presence of infection granulation, or even scar tustue, is indeed a bizarre expectation. Furthermore, bone does not show any demonstrable evidence of regeneration beneath adherent aplit thickness grafts as the cavities remain essentially the same size for an indefinite period of time, Previous efforts to obliterate septic cavities by anti septic paste fat muscles and pedicle grafts have also proved unsuccessful.

The authors present a small series of 23 cases which were operated upon in three stages (i) thor ough sequestrectomy and excision of scar (s) early split skin grafting and (3) bone grafting followed by immediate application of a full thickness pedicled graft.

The first stage is that of acquestrectomy and prep-326 aration of the cavity All cicatnical soft tissue must be excised Eburnated bone or cartilage if the de fect is near a Joint must be saucenzed in its entirety The wound is then packed with vascline gauxe and the limb is encased in a cast. At the end of 5 days the wound is inspected and if an exuberant grand lation is noted on the bony cavity a split grafting operation is done to convert the compound wound

The second stage comprises the application of a into a closed one. split thickness skin grait The recipient area is curetted of any nonviable or granulation tissue, and a split thickness graft from oro to or6 of an inch is obtained and placed over the defect. A pressure dressing (Koch's) is applied on the wound Immobil hration is effected by a spilnt or cast. Chemotherapy counsting of penicillin or sulfonsmides is administered for 3 days. Under this regime from 80 to 95

per cent skin take has been observed The third stage consusts of obliteration of the bone cavity with sutogenous bone chips. The principal

I Planning of a suitable full thickness covering factors of this stage are

a Complete excision of the split throkness cover ing from the depth of the saucerised bone defect for the defect 3 Procurement of sufficient bone chips from the illac crest or other suitable sites to fill the cavity

4. Covering of the chip filled cavity with skin and auboutaneous these without skin tension and placing completely

onteogenic consolidation of the defect can be the suture line on sound bone. further enhanced by curetting the cavity and opening both ends of the medullary canals. A pressure dressing of machinist's waste is again applied sutures are removed in 6 days chemotherapy is continued for from 3 to 5 days, and immobilization is main-tained until bony union is obtained.

Accompanying the article are many excellent photographs of the technique and numerous roent processing of the technique and numerous rocat

The complications encountered in the 25 cases were hematoms in 2 tibles, suppuration in 1 tibis, and femura and a draining sinus adjacent to the operative site In a femur

Gillis, L. Nearthrosis of Humarus Shaft for Ampu tation at the Elbow Brit. If J 1945 2 686.

The author describes a new operation for making a joint in the shaft of the humerus for cases of am nutation at or near the elbow joint. According to this article it is no longer necessary to amputate an arm at the orthodox site of election, i.e. 7 or 8 inches below the tip of the acromium. It is to be remem bered that the forearm resected at, above, or below the elbow joint can now be fitted with a useful

As its purpose the operation is designed to ac complish two distinct functions (1) to conserve the prosthesis.

muscular power of the flexors and extensors of the forearm and to harness that function and (2) to make a new joint in the shaft of the humerus at least 4 in. below the shoulder which should possess the property of complete extension and a varying degree of flexion.

The author has performed 24 such operations. The first 8 of these necessitated a second inter vention for removal of increasing ankylotic bone callus in order that bony union of the new joint be prevented The technique was altered as follows I A posterior muscle splitting incision from a to 314 inches long was used

2 From 11/4 to 2 inches of the humeral shalt were removed with a gight saw

The ends of the bones were bevelled at an angle of 45 degrees in front to permit the manmum degree of flexion

4. The medullary cavity of the bones was curet ted and packed with bone wax.

The bone ends were fulgurated and sulfanis mide implanted in them. This step is considered important by the author as it vitlates ostrogene-

The postoperative management comusts of the application of a straight plaster of Pers cast for 3 weeks, active and passive motion of the new forearm, and the application of a figure 8 crepe

In addition to several illustrations, the article contains 5 detailed case reports depicting the technical perplexities encountered in the original opera tions and their solutions.

The results in 10 cases show uniform function of flexion and ability of the patient to touch his face and back of the neck without pain. Six of the st patients have acquired varying degrees of active flexion and the cond ton is still improving. Func tional results in the first 8 cases (operated trace were not noted

# FRACTURES AND DISLOCATIONS

Effic, J 8.1 Wounds in the Region of the Hip Joint

The unsatisfactory results in a group of 44 wounds of the hip-holnt and high femoral fractures treated in the base hospital attended by the author prompted a review of the methods used and led to the suggestion

In 1914 to 1918 the mortality in this group was 60 per cent, accounted for largely by visceral inof improvements. juries and a still hip with shortening and often per sistent draining sinuses was accepted as the until result. Recent Russian writing advocates radical surgery with early resection of the Joint or disarrangement of the Joint of the Joint or disarrangement of the Joint of the Joint of the Joint of the Joint of the Joint

ticulation at the hip, to control toxenia. The patients were received from 1 to 4 weeks after injury and had either obvious wounds of the hip joint or fractures in the area of the neck or trathanter with doubtful penetration of the hip joint Twenty two patients had been or still were toxenic when received. All had been explored and foreign fingments had been removed including many bone fingments. Plaster spices or Thomas spinuts were used for transportation and usually changed en route at the receiving hospital where some wounds were re-explored. Systemic administration of suitonandes and penicillin was done routinely. The base hospital employed skeletal traction in Thomas spinuts and plaster fixation about equally. Sequestrectomics and 5 major drainage operations of the Gudlestone type were done.

Ankylosis of the hip occurred in 13 of the 16 cases in which the hip joint became septic. In 16 patients the wounds were unhealed at 6 months. Six patients

had I inch or more of shortening

Slow healing is due to inadequate primary drain age which makes delayed primary suture impossible and later to failure to recognize early the need for sequestrectomy or drainings of hidden abscesses. The use of penicillin massix the presence of undrained pockets and this must be remembered in appraising the situation.

The shattered femoral head must be removed

early to facilitate healing

Shortening is inevitable in head and neck fractures but traction rather than plaster immobility attento overcomes the tendency toward bowing and hortening in trochanteric incutures Early knee motion is of great importance and need be delayed only when the desire to encourage hip fumon requires plaster immobilization rather than traction

in a Thomas splint.

No life or limb was lost in this series but in retrospect, morbidity might have been reduced by the knowledge gained and summarised here. Roent genography before primary treatment is desirable to determine the status of the fracture especially as to whether the femoral head is involved. Bone frag ments should not be removed freely unless they are all or part of the femoral head Rectal examination a emential to help establish the extent of possible intrapelvic injuries. A minimum of skin should be erened-no skin should be sutured-and a plaster spice should be used for transport. Systemic chemotherapy of course is used early and a "booster" dose should be given again before each change of cast or other manipulation to inhibit flare up of the infection.

Adequate later treatment necessitates removal of the cast and careful estimation of the patient a general condition with reapplication of the plaster spice only when analysiss of the hip is desired Constant vigilance for abscess formation or the presence of foreign bodies or sequestra, with prompt largery will prevent persistent sinus drainage and lease the morbidity. Early appreciation of the case requiring radical treatment for deep seated infection, and prompt surgery of the Girdlestone tripe will save life and reduce morbidity. In the author's experience the end result of this treatment has been satisfactory.

FRANCES E. BRENYFORE, M D

Godoy Moreira, F. E. Difficult Fractures of the Neck of the Femur Treated with the Stud Bolt Screw Simplification of Technique. J. Bene Surg. 1945. 27, 595.

In July 1940 the writer reported a technique for treating ununited fractures or otherwise difficult cases of fracture of the neck of the femur with the stud bolt screw. Since then the technique has been amplined. A hand drill has been substituted for the motor drill and the hard cortex is perforated by a hand driven burr preliminary to the insertion of the stud-bolt screw.

Eighty patients have been treated by this tech nique with excellent results and 8 case reports are presented illustrating that good union and function may be obtained. One patient, a 6c year old female was operated on 2 days following fracture of the femur. Four months later she had perfect union with normal function. The remaining 7 patients sustained fractures from a to 18 months before operation, the youngest being 40 and the oldest 70 years old. Of the 7 6 obtained good union and perfect function while in 1 a 70 year old male, nonunion persisted but the patient was able to walk a miles easily. This good result is attributed to achieving solid osteosynthesis by means of the screw. In 2 instances osteotomy was performed at the same operation as an aid to union

A short plaster spica is applied to the knee 20 days after operation and the patient is permitted to walk the spica is removed 40 days afterward

RUDOLPH S. REICH M D

#### ORTHOPEDICS IN GENERAL

Howard J E Parson W., and Bigham, R. S., Jr.; Studies on Patients Convelector from Fracture The Urinary Excretion of Calcium and Phosphorus Bull Johns Hopkins Hosp., 1945

The calcium and phosphorus metabolism with special reference to Ca I concentration in the unne was studied in a group of 17 patients. Thirteen patients were convalencing from femoral and tibial fractures and 4 were studied before and after femoral osteotomy for slipped epiphysis.

This study was made in an attempt to explain two frequently observed conditions in recumbent orthopedic patients (1) nephrolithlasis and (2) a lack of time salts in the bones of limbs immobilized for long

periods of time

A steady rise in the calcium output in the urine was noted. It reached its maximum approximately it month after injury. The peak of exerction of calcium was maintained for an indefinite period. It usually began to fall when the immobilization was discontinued.

A similar pattern of urinary calcium exerction was observed in patients who had had a femoral oxteotomy. The peak of calcium exerction, however, was reached much earlier. In patients who had suffered a fracture x rapid breakdown of protein occurred.

with the excretion of large amounts of nitrogen. The maximum amount of urinary excretion of nitrogen was reached in from 5 to 7 days. It subsided in from 25 to 40 days.

Maximal curretion of calcium in the urine oc curred in every instance at a time when the urinary output of nitrogen had returned to normal. The same reciprocal relationship between maximal diuresis of calcium and nitrogen had been observed in patients subjected to femoral outerous.

The type of injury (simple or compound fracture) and the patient's age, height, and weight or hoay structure (heavy or light bony frame) had no bearing of the urinary output of calcum. The increase or decrease of water intake had no influence on the amount of calcium output in the urine. Alkalinias tion, sulfadiasme, or sulfathiasole did not change the level of the calcium exerction.

Large shifts in detary calcium affected the urinary output of calcium very little. An increased or diminished intake of calcium in the form of calcium lactate had a somewhat greater influence upon the calcium dimens than the intake of calcium in the

form of milk.

Vitamin D<sub>2</sub> (calcifered) in varied doses, with or
without an increased intake of calcium, did not
significantly change the calcium excretion in the
urine.

The rise and fall of intake of inorganic phosphorus showed similar changes in the urinary output of

phosphorus.

The blood constituents of the patients showed no significant changes in the hemoglobin, red blood count, blood volume, calcium and phosphorus levels,

and alkaline phosphatase concentration. The theory that a decreased blood supply causes increased bond density and that hyperemia of the part results in skeletal rarefaction is challenged by the fact that reduction of the blood supply causes atrophy of the issue supplied. Unliateral humbar sympathectomy in children caused the leg on the same side to improve its growth in most instance. This influence on the growth of the leg is exercised by the control of its blood supply. There is experimental evidence that venous obstruction accelerated fracture healing by speeding the formation of callus. Growth I. Rens. M.D.

Beliboni, V. G., Shapiro, I. M., and Kydd, D. M.: The Penetration of Penicillin into Joint Fluid following Intramuscular Administration. Am. J. M. Sc. 1945, 2 o. 588.

Seven patients with hydrarthrosis affecting one or more joints were studied 5 had typical rheumatoid arthritis and 2 an atypical disease which was probably also rheumatoid arthritis. In only 1 case was the joint severely inflamed. Four of these patients received 25,000 units of penicillin in 25 ml. of mor mal saline solution administered intransuscularly every 3 hours and 5 received 40,000 units. In each instance samples of serum and joint fluid were obtained simultaneously X 1 2 and 3 hours after the

patient had received the eighth dose of pencilla. In a instance, however the samples were obtained 3 hours after the sixteenth dose, and in Instance, material was obtained 3 hours after the treaty fourth dose. The concentration of pencillain hoth the blood sens and the joint fluids from these patients were determined by the cop assay method as themse were determined by the cop assay method as

then were determined by the cup assay method as modified by Cholden (J. Bart. Balt., 1944, 47, 403.). In all cases penticilly was found to penetrate readily into the joint which remited in that esentially equal amounts of the penticillae intered the joint fluid and blood serum: I hour after its administration. In the case of the serum concentration, it is true, they fell rapadly after I hour and at the end of 3 hours little or no pencillan was detectable in this body fluid however in the joint fluids the concentration of pendicilla descreased more slowly there being appreciable amounts of pendicilla present 3 hours after the administration.

According to Rummeltamp and Keeler the effective concentration of penicilin in the blood a cylindry and the control of Forey unit per milliller and in the serum, and Forey unit the joint find of the cases studied because the bour after the administration of penicilin showed amounts of penicilin warying from onto the output per milliller and the determinations made 3 hours after administration in 6 of the 79 thems showed that it still contained from one to

The authors conclude, therefore, that the amounts of penicillin which are antibacterial for the common pathogens invading joints are obtained in the synoval fluid by the intramuscular administration of penicillin in the doses discussed.

Penicillin did not tend to accumulate in the joint fluid. Joen W BREENEAR, M.D.

Berans, M.; Changes in the Musculsture of the Gastrointestinal Tract and in the Myocardium in Progressive Muscular Dystrophy. Arch. Path. Chic. 1945 40 225.

In this article 4 cases of progressive mescular dystrophy are reviewed, with special reference to lesions in the myocardium and in the smooth macket of the gastrointestinal tract. Progressive muscular dystrophy has been regarded as an intrinsic disease of the muscles. More recently the disease has been classified as a disorder of the autonomic nervous system.

In the past many workers have found diffuse scarring and deposits of fast in the myocardism of patients afflicted with progressive muscular dystophy. Many others denied having found any pathological changes in the myocardism or gastrontential tract in these cases. Other investigator described a cardiolatestial syndrome in patient with progressive muscular dystrophy which was accompanied by vomiting generalized adolonial tendemess and pain, diarrhes, suchyardis, and signs of cardiac failure. One author found roat genological changes in the exophagus similar to these described in alteroderma.

A detailed account of the history physical find ings, the course in the hospital, laboratory data and antopay findings is given of the 4 patients with progressive muscular dystrophy. All of them died of pulmonary complications. The disease was usually discovered at the age of 4. It terminated with the death of the patient from 10 to 16 years later. The treatment of most of these patients consisted of the administration of acetylcholine, aminoacetic acid vitamins B and C, and other purely supportive symptomatic measures.

All of these patients showed considerable wasting of all of the skeletal murdes on admission to the hospital. No muscular fibrillation was observed. Contracture of the muscles especially of the plantar aponeurosis, gastrocnemius, and hamstings was seen which placed the lower extremities in a froglike position. Abnormally increased mobility of the shoulder, hip and small joints of the hands was found. In most cases reflexes were absent. The electrocardiogram showed a right axis devlations and tachycardia in a few of the patients. The roentgen ograms revealed moderate decalcification and considerable underdevelopment of the bones. In some instances the esophagus was slightly di-placed by a dilated right suricle.

The laboratory data were normal except for a somewhat lowered basal metabolic rate in some cases.

On the autopsy table the muscles were found to be pale thin, and streaked with yellowish fat tassue In most cases the gastroenemus, recti pectoral illopsous and intercostal muscles were most seriously affected in the order mentioned. The beart was found to be hypertrophied and the endocardium was

thickened and streaked with fibrous bands. Some sections of the myocardium and papillary muscles were found to be completely replaced by scar tissue

Alicroscopic examination of the skeletal muscles showed changes usually found in progressive muscu lar dystrophy. Large channel-like structures showing disintegrated muscle fibers in their lumens and capillaries in their walls were very significant. Such structures probably represent the persisting perimysium after the muscle fibers have disintegrated Other findings were great variation of the size and shape of the fibers, vacuolation and clumping of the sarcoplasm and proliferation of the nuclei of the sarcolemns.

Sections of the myocardrum and papillary muscles showed hyalinization fibrosis, interstitial hemor rhages surrounded by mononuclear cells with phagocytosed red blood cells. The lower part of the esophagus showed considerable edema of the lamina propria, and the epithelium was irregularly desquamated The small intestine showed similar changes in the muscular layers. In spite of the edema the width of the walls was greatly reduced and the muscular layers were atrophled. The rectal mucosa exhibited infiltration of red blood cells and areas of autolyzed mucosa. The muscularis mucosa lavers were fragmented. The longitudinal and carcular layers were atrophied and the muscular fibers widely separated

No lesions of the smooth muscles of the vascular system or of any other organs were noted. With the exception of the presence of thymic tissue in 1 case no abnormalities of the endocrine glands were observed.

## SURGERY OF THE BLOOD AND LYMPH SYSTEMS

#### BLOOD VESSELS

Gurdjian, E. S., and Walker L. W: Traumatic Vascepastic Disease. J Am II Am 945 120

It has been known for some time that workers exposed to repeated percussion may develop circu latory disturbances in the hands. The condition is most frequently associated with the use of the pneu matic hammer or jack hammer Pneumatic hammer disease has become synonymous with white fingers, dead fingers, traumatic vasospastic syn drome, vasospastic disease of the hands, and Ray naud a disease

The first report on pneumatic hammer disease was made by Longs of Rome in 1911 while the first report on this condition in this country was made by Cottingham in 1917 Hamilton described the clinical findings in detail in 1918 after studying the problem arising out of a dispute between Indiana limestone cutters and their employers over the use of the

nneumatic chisel.

The clinical pattern of traumatic vasospastic disease of the hands is almost stereotyped. After a few months to several years of exposure to the vibra tions the patient notices attacks of blanching and numbness of the fingers. The pallor is much more pronounced than in Raynaud's syncope but it is not succeeded by the stage of extreme asphyxia so characteristic of the latter. It is not symmetrical even when in both hands.

The attacks may occur while the patient is working Usually the blanching is most pronounced early in the morning particularly in cold weather The attacks can be brought on by washing the hands in cold water or by going outdoors for a while in cold weather They usually come on more frequently in the winter months, when exposure to cold is more apt to occur Emotion does not appear to produce the attacks. The attacks do not result in wasting and death of the tusue. The workers are also sublect to Raynaud s and Buerger s diseases and hemiparesthesias not caused by the vibrations

The present study is concerned with the clinical findings and the microscopic findings in the capil laries and arterioles of the fingers in 6 women war workers using a pneumatic riveter in airplane con struction work in Detroit. The authors do not state the percentage of women affected in this occupational classification but to their knowledge this condition has not been described in women previously Mi croscopic studies of the finger tips have not previously been reported Serial sections of biopsies of the finger tips of 5 of the 6 patients showed no path ological changes except in two sections, revealing a red staining amorphous substance in the capillary

The mechanism of the disorder is as yet unex plained The possibilities mentioned are low tem perature of the surrounding air at the place of work anemia of the hand from holding the air hammer too tightly and injury to the myoneural junctions of

the arterioles in the fingers

The clinical course of these patients has been characterized by attacks of benign vascepasm with little increase in severity over a period of all year of study The discontinuance of the use of the poenmatic hammer has not resulted in a single case of

In the discussion de Takata stated that he be heved that tools having a high vibration rate may produce a percussion neuritis. He mentioned Denny Brown a experiments with a single percussion of a nerve trunk which indicate that the damaged myelin escapes from its sheath futo the endoneural space and sets up an irritative internal disorganitation of a mixed nerve which results in causalita with its inco-ordination of circulation

JOHN E. KINNY VINCE, M.D.

Elkin D C., and Kelly R. P: Arteriorenous Aneuryum. Ann. Surg 1945, 12 529.

A near disaster from hemorrhage from the posterior tibual vessels in the course of the exclusion of an arteriovenous aneurysm prompted the authors to modify their approach to these vessels and remove the upper portion of the fibula, with resection of the head of that bone when it became necessary The collateral anastomosis which develops as the result of arteriovenous communication together with dilatation of the vessels, including those which per forate the interesseous membrane demands direct visualization of these vessels and their careful ligation and division. Otherwise the retraction of vascular channels through the interesseous membrane may result in serious or even uncontrollable hemorrhage and necessitate a second incuion along the front of the leg or the removal of the fibula in the presence of hemorrhage and at an inopportune time during the course of the operation. While this operation has been performed primarily as an approach to arterior enous fistulas and aneurysms of the posterior tibial vessels it is of equal importance to realize that the same approach is necessary to reach the anterior tibul and peroneal vessels in the upper part of their course. The authors prefer continuous spinal anesthesia for the procedure.

The operation is described in d tall with illustrations of the technique. There are 15 case reports given with the preoperative findings. It is interesting to note that enlargement of the heart is not present in all cases, but it is found in some of them and seems to depend upon the length of time from the injury

to the examination made before surgery The authors conclusions are as follows

Careful exposure of the tibial and peroneal vessels in the upper part of their course is necessary in the

#### MISCELLANEOUS

Sarmiento P B : Some Consideration Concerning the Surgical Treatment of Elephantiasis of the Extremities (Algunas consideraciones sobre el tratamiento quirurgico de la elefantiasis de los miembros). Rec espan cir tranmat ortop 1945 3 146

The majority of authors agree that a primary irritation of the lymphatics predisposes to a septic infection which in extreme cases may lead to elephantusis. The condition is characterized by an exidate rich in leucocytes fibrous hyperplasia and thrombosis and obliteration of the blood vessels in the subcutaneous tissues. In many instances no streptococci or parasites can be found and a special susceptibility of the lymphatic or lymphonenous system must be assumed. The causes of such abnormal conditions of the lymphatics may be of a local or general character

As to the treatment of the condition Cornachan suggested ligation of the main artery but the result ing necrosis soon discredited this operation Wintwarter recommended a gradual compression of the main arteries but the same objection may be raised to this procedure as to ligation of the main artery Buchoman suggested ligation of the main vein of the involved extremity while Leriche recommended a periarteral sympathectomy basing his recommen

dation on the hypothesis of the existence of sympa thetic fibers in the lymph vessel walls. Rogers ad vocates extensive removal of the involved tissues and insists upon the necessity of reneated interventions. Hanley described a procedure which he calls "lym phangioplastic, consisting of the introduction of silk fibers into the affected zone and extending them into normal regions. In this manner he expected to establish artificial capillary drainage from the in volved to the healthy tissues. Le Dantec supple mented Hanley's procedure by immunization with a certain vacance Walther buries rubber tubing in the involved tissues while Lans extirpates extensive portions of the tissues and introduces fascial strips in order to establish drainage. Kondoleon suggested an externation of the aponeurous in order to facilitate deep drainage. Payr and Oppel described simi lar methods. Castellani advocates daily injections of fibrolysm or acetosalicylic thiosinamine. Mata recommends the administration of strentococcus vaccine before any operative intervention.

The author operated on a 39 year old woman who developed a suppurative process in both inguinal regions at the age of 15 years. Following these lesions a tremendous elephantiasis of both lower ex tremittee gradually developed. The author believes that repeated infections in the form of dermatitis. probably of a streptococcal origin led to an infection of the lymph glands and lowered the resistance of the skin. Apparently repeated dermatitis with resulting lymphangitis produced cutaneous alterations and changes in the lymph vessels.

As to the treatment the author employed a procedure consisting of resection of a large amount of tissue. He followed Sistrunk's technique modified by kondoleon. In extensive cases of elephantiasis the operation must be performed in stages.

The author resected 95 kgm of tissue under spinal anesthesis from the left extremity and a similar amount from the right extremity Catgut No o was used for ligatures and the tissues were approximated with catgut No 3 A check-up 8 months later showed very satisfactory results.

#### ANTISEPTIC SURGERY TREATMENT OF WOUNDS AND INFECTIONS

Laiich J J., and Mason J M., III: Resuscitation of Severely Wounded Casualties Surgery 1945

During the North African and Tunisian cam paigns and the Anzio-Nettuno beachhead operation in Italy a great number of severely wounded casual ties were observed. Many men came into the receiving tent with a blood pressure of o/o. Their condition was judged by the manner in which they responded to transfusions of plasma and whole blood It was believed that in cases in which the systolic pressure rose to 80 mm of mercury and remained at that level the chances that the individual could under go a major operation would be quite satisfactors However in cases in which there were compound head injuries penetrating wounds of the chest or abdomen, or compound injuries of the femur it was more difficult to get the casualties prepared for surger. It was felt that plasma or blood could be given fairly rapidly. When the degreed systolic pressure was not maintained reasonably, the patient was given a high priority for surgery. Hemorrhage was the greatest cause of a drop in the blood pressure in this group. Infection and cardiorespiratory embarrassment must be combated intelligently in association with severely wounded essualties. If and when the systolic pressure dropped in the preoperative and surgical phases of treatment, during the time blood or plasma was being injected the drop in pressure was combated by increasing the amount and rapidity of the infusion

When the systolic pressure reaches 100 mm, the patient should be given an additional 500 to 1000 c.c. of blood, either preoperatively or during surgery before resuscitation is considered adequate.

Three cases are reported in detail to illustrate the

points brought out.

RICHARD I BERRETT JR. M.D.

Rawles, B W 1 A Routine for Early Skin Grafting of Deep Burns. Surgery 1945 18 696

This article presents the experience in the treat ment of a group of 154 patients with burns in an overeess U.S. Army General Hospital in Italy during a period of 14 months. Forty two or 37 2 per cent of the burn cases, required grafting as compared with 54 per cent of a group of 78 burn injuries proviously reported the great difference being due to the position occupied by the hospital in the chain of evacuation during the two periods. In a number of instances the burns were associated with injuries

of the nerve bone and soft parts since 33 per cent of the patients had been wounded in action. The author's study deals primarily with the late manage ment of deep burns since a majority of this group received the initial treatment in other medical installations and were transferred to this hospital from a few days to several weeks after the injury

The control of infection is of paramount importance at this time if prompt healing with early and successful grafting when indicated is to be accomplished Infection besides jeopardizing the life of the pa tient complicates the successful treatment of burns in the following ways (1) the healing of second degree burns is delayed (2) deep second degree burns with sufficient viable epithelium for complete coverage may be converted into third degree burns (3) in third degree burns deeper destruction of tissue occurs with an increase in scar tissue forma tion (4) grafting may have to be delayed unnecessarily and may even be unsuccessful and if so is followed by the formation of more scar tissue and contractures and (5) even after the successful take of grafts, furuncles and pustular infection delay the healing of small uncovered inbetween areas and destroy portions of viable grafts days or weeks later The problem therefore in burn therapy after shock has been overcome is to control injection and obtain a closed wound as rapidly as possible either by the healing of undestroyed epithelium or by skin grafting

Penicillin is used in the primary treatment of burns and is given intramuscularly in doses of 25,000 units every 3 hours. Infection is controlled in the majority of cases, provided the primary dressing is left undisturbed for from 12 to 14 days. It is the author's impression that oral sulfadiazine is just as dependable as penicillin during this stage of the treatment. Any drug therapy is only an adjunct to good surgical management (originally described by Allen and koch) and briefly consists of (1) metic ulous cleansing of the burned surface and (2) a resilient pressure dressing with fine mesh grease gauze next to the burned surface. This should not be changed for from 12 to 14 days. Care is taken to aplint adjacent joints and in the case of the extrem ities, to see that the pressure dressings begin at the toes or finger tips and extend well above the burned area. Elevation of temperature occurs when this routine is used but only on rare occasions is it necessary to change the primary dressing any ear lier than 12 to 14 days for the purpose of inspection All dressings are done in the operating room under strict surgical technique and if the burns are at all extensive, with the aid of an anesthetic. A majority of second degree burns are found healed when the primary dressing is removed and there is only min imal contamination or infection in the case of deep burns. All loose, dead skin and the tops of unbroken plisters are removed in unhealed second decree burns, and a second petrolatum gauze dressing is applied and left undisturbed for another period of 10 to 14 days. Healing is complete in the majority of the remaining patients when the second dressing

is removed, except when there are areas of full skin INTERNATIONAL ABSTRACT OF SURGERY is removed, except which had not been previously

cognition of full thickness burned skin and its Prompt temoral is necessary if grading is to be in prompt removal is necessity if Resiling is to be done early. The identification of nonvielle skin by concerny the menuncation of nonvasor skin by means of sodium shoreseedn and the exchange of sodium shoreseedn and the exchange of sodium shoreseedn and the exchange of some state of the state of the solid state of the soli ment of sodium interests and the crosses of such areas followed by immediate starting when such area, louower by immediate statute when the burn is first seen or at the time the first or second the burn is first seen or at the time the first or second dreading is done has been suggested. Rubin, L. R.: Configuous Elda Flaps for Wounds of the Establishee. Am. J. Say 1915, 7. 35 Closure of avulsed wounds in which the loss of Course of avalent wounds in which the ion of the use of tube and fast afternive may be effected by the course of tube and fast after a two per effected by against with the aid of after attempts to som-charts, his experience with to selected was weards, and charts, bit experience with so selected was remaind charts, in expensive with 50 selected was worked to the various configuous akin flap techniques.

The skin adjacent or continuous to a wound in no the adjacent or contiguous to a wome a mobiled by the use of planned incisions which per a fire also a fire a f modified by the use of planned inclusions which per mit the continuous akin to cover the defect after almit toe contiguous and to cover toe cover after so-Valuement, rotation, or transportation of the season fig. Often extensive endermining opens large treatment of the contract of deposition of the control of the con of these to become investor, but chromotomy with penicilli, reduces the hand time particularly with periodicity, reduces the matter.

The author has also made use of multiple trans-

Any attnorman and made use or murape trans-fractions, where indicated, to air wound healing. This technique is applicable to wounds required movement stems which for the contract frequency. them and transpared as appearance as revenues required to senting a senting of the senting and new sein ausme which (1) will cover exposed done, in and a principal manele defects (1) will only a subsect to moderate manuals when four for mixture. and (a) will not consider the first back to make the same of the s and the contract contract the contract that skin manipulation beyond a certain point will that here manufactured overtime a certain point among the blood supply as to four the ore of continuous as in Real Property as to four the ore of the continuous as in Real Property as to four the continuous as in Real Property as to four the continuous as an alternate wheel contiguous skin flaps. To assure an adequate blood supply the sape must contain all layers of fat down supply the major most contain an inverse or in toward to the deep facts. The flaps are most successful to the word black. The haps are most succession where the skin is larges on the abdomen, hark and face. Only clinical indemnent determines the limits stress can same at any as on the appropriate face. Only clinical indigeness determines the limits

Buried absorbable autures along with plaster of Paris aplints are used to relieve the tention at the darn spunts are used to remove the transce at the edges of a wound. Planned incircors are made along cuges on a women. Figures memors are more asset and irregular wounds are transformed

into geometric designs (triangles and rectangles). Closures are effected to give figures H, Y Z, T etc. Wherever the position of the flap necessitates carting arcses the main sources of blood supply the author employs the technique of delaying which uses the principle of a gradual, rather than a sudden reduce through the akin, subcutaneous tissue and fat, is completely lifted from its bed, only to be replaced immediately and resultured in its former position until the blood supply at the base becomes adequate. This may require multible stage operations.

Local anesthesus, even without adrenalm should never be used. The injected fluid acts as a mechan ical barner to capillary circulation and of course adrenalm is contraindicated because of its visuocon stricting action. Brachial block for the arms and spinal anesthesis for the lower extremities are recommended. For individuals with a high vascular torse, who are sensitive to the visuoconstrictive effects of cold, pain, and trauma use is made of lumbar paravertebral block (below) and stellate block (above)

Direct heat to an ischemic area favors necross because the local metabolic needs are more greatly mcreased than is the blood supply. Nevertheless, heat applied to the trunk of the body is beneficial by virtue of reflex vasodiliatation in the extremities without an elevation of the local metabolic needs.

In instances of associated nerve injury it may be best to use a split skin cover immediately and to defer the flap closure until the nerve has been repaired.

The contiguous skin flap is designed primarily for utility and no attempt is made to obtain a counctic result.

DAVID H. LYEN M.D.

Newman, P. H.: Early Treatment of Wounds of the Knee Joint. Lascet Lond., 1945, 249, 632.

This article deals with the treatment of wounds of the knee joint The author classifies these wounds as alight, moderate, and acvere, of which there were 10 30 and 8 respectively He discusses the diag

nears of the type of joint injury and the treatment. In the first group application, intra-articular penicilin, and immobilization by means of a plaster cast was found sufficient. In the second group careful wound inchion, primary sture, intra-articular and parenteral administration of penicillin with immobilization and extension in the Thomas splint were instituted. Among the 4g cases in these two groups there was only z case which gave him much difficulty

In the remaining 8 cases falling in the "severe classification because of the time element and con tamination 5 of the wounds were left open. The other 3 were closed and treated the same as those in the first 2 groups.

Foreign bodies were removed at the first operation whenever this procedure was reasonable and possible. A separate incision was found to be necessary in a few cases. The importance of preoperative

roentgenographic films was stressed. The author also calls attention to the fact that nonradiopaque foreign bodies such as wood and glass may be a source of trouble. Frequently the history of the accident will put the surgeon on his guard in the last type of case.

PAIR MERSELY, M.D.

Caldwell, G. A.: Secondary Infection of Wounds.

Ann. Surg., 1945, 122, 641

Secondary infection following the original infection of an open wound is so commonplace as to pass innoticed. The average surgeon accepts it as a marter of course and unless the patient s life is endan gred or ha leg is about to require immediate amputation he thinks nothing need be done to improve the situation Actually secondary wound infection is the principal cause of delayed healing and impaired function. Moreover such infections are to a great extent preventable and even established in fections can frequently be eliminated

Primary wound infections (to distinguish them from the secondary) are those caused by bacterial contamination at the time of injury. These bacteria are derived from soil, clothing skin and foreign

bodies

Secondary infections are those caused by bacteria introduced into the wound at any time after the initial injury. These invaders may come from the skin of anyone touching the wound from unsterile in struments or dressings, or from the respiratory tract of the patient or of his attendants. They may fall into the wound with dust from the floor of a ward and may be drawn by capillary attraction through a soggy dressing which is in contact with solded lines

Only 5 per cent of fresh wounds were found to be infected with hemolytic streptococci and staphylococci and bacillus pyocyaneous upon admission to the hospital, but after a week in the institution 50 per cent of the wounds contained secondary invaders and later on they were found in from 70 to 80 per

cent of the open wounds.

Pathogenic organisms can be eliminated in most case by the body's defense mechanisms when these are aided by adequate surplical debridement. They eraist as serious or trivial infections in from 10 to 25 per cent of cases. They appear as new invaders and produce serious and trivial infections in from 20 to 50 per cent of cases. Of the serious persistent in fections developing in wounds probably at least half are caused by becteria secondarily introduced.

In view of these facts the "lasses faire" attitude of suggeons toward secondary wound infections is not justifiable. Surgeons are correct in placing major emphasis upon the general condition of the patient and adequate drainage but are incorrect when they ignore the changing bacterial flora in the wound under treatment.

Detailed modes of treatment including meticulous operative technique supplemented by the admin stration of sulfonamides or penicillin before and after operation are described and illustrated by cases

HARRY W TINE, M.D.

INTERNATIONAL ABSTRACT OF SURGERY Birks, P. M.: Infections of the Superficial Palmar Space Lance Lond 1945 249 669.

The author presents 5 cases to illustrate the effects And aumor presents 5 cases to interest our of incorrect and correct management of infections of or morrors and correct management or infectious or the superficial palmar space. These infections have sained little recognition by virtue of their compara samen near recognition by virtue or their compara-tive rarity and the III defined anatomical nature of the space. The space lies in the hand between the the space, the space was in the many verteen the palmar fascia and the flexor tendons, proximal to parinar lascia and the mean tenuous proximes the transverse crease of the palm. It is doubtful if the transverse crease or the paint, it is document it exists in the normal hand. According to Iselin, the boundaries of the superficial pretendinous central palmar space are Anterior the palmar fascia

Posterior the tendons and lumbrical muscles Internal the fourth intermets carpal space

External the union of the palmar fascia with the intermuscular aponeurosis of the second metacarpal Proximal the union of the paimar fascia and transverse ligament

Pistal the fusion of the middle palmar aponeu rests with the superficial transverse ligament Fluid injected just through the palmar fascis mixes feely with fluid injected through the web of mixes treety with many injected through the wood the middle finger into the middle pairmer space. However indefinite this space may be in the normal hand a collection of pus behaves as though it was confined between tendons and palmar fascia. In the carly stage extension of the infection occurs princi pally through the palmar fascra

Cluically in from 3 to 10 days after injury the hand becomes painful and the paim sweller and pecially proximally and a purulent blister collects under the skin. The fingers are semillaxed active movements are restricted and painful there is little

edems of the dorsum but a great general upset.

The abscess should be opened before the palmar fasca sloughs (that is, early) under unhurried anesthesis and with a tourniquet. The incision should be over the most prominent part of the swelling and in the line of the crease. The fascia is opened with ainus forceps. The superficial palmar arch under the anna roveps. The supermust parmar areas under the fasca is pushed out of danger by the pus. Tuberare unnecessary for drainage. The after care consists of

immobilization on a wire aplint with frequently DAVID H. LYNN M D

Pract, E. L.; Glinkal Tetanos. J in M in

The classification of 56 children with tetanes in the order of the severity of their infection was of the the order of the seventy of the importance was or use in crainating the methods of training emporen.

There was no evidence that amounts up to 80,000 Andre was no evidence that amounts up to concern and of tetanus antitorin was more effective than amounts of 30,000 units. The intratheeal adminaamounts or some more traction of tetanus antitoxin was probably but no definitely more effective than the intramuscular or intravenous administration of the same amount of

Fatal reactions occurred from tetanns antitoum arven intrathecally to some patients, who in all likelihood, would otherwise have survived their tetams infections. Hence, tetams antitoxin should not be used intrathecally in any but the most severe not be used intractive any one are more access, if it should be used at all, until a preparation is available which is incapable of producing screen

Extraion of the site of infection, once clinical symptoms of tetanus were present, did not smello rate the course of the disease.

Neel IL B., and Cole, J. P.; The Bacteriniary of War Wounds in the Pacific Area, U.S. Yea.

A hospital ship in the Pacific area treated 2 740 fresh battle casualties in a little over one year. Cal ture of all of these wounds was highly desirable, but physically impossible because of the abortness of time, the large number of casualties and the large laboratory personnel. One hundred and sixty-one cases had wound cultures. These were severe wounds caused by shell fragments in 86 patients bullets in

In contrast to civilian wounds, which are usually seen by a surgeon within a few bours these wounds did not receive treatment for from 24 to 48 hours because of the ferocity of battle and the difficulties secure of the terocity of basic and the distance of transportation. Eighty three patients in this group had their wounds cultured and were under

treatment within 34 hours. An additional 30 patients were seen during the second 24 hour period.

Whenever possible, tissue was taken from the wound for culture. When it was not available, swab cultures were made on blood agar and tryptone broth for acrobic organisms. For anacrobic organisms, a destrose agar stab bested at 70°C for ro minutes, a meat infusion med um, a destrose-gar tab unheated, and litmus milk were inoculated

The authors attention was centered on anseroble cultures, and 160 wounds were cultured for amerobic organisms. Of this group 77 (48.12°c) were positive.
The most frequent anserobe cultured was the clostridium perintum, present in 57 of the 77 wounds.
Unclassified proteolytic anscrobes were present in 24 cases, and 23 wounds yielded more than one species of anarobe. Clinical gas gangrone developed in 37 cases (35% of the anaroblesily infected wounds.) and in 1 case which failed to yield anaerobes on the

admission culture. Clostridium periringens was the offending organism in 26 cases of gas gangrene while the other case was caused by the clostridium

septicum.

Direct smears from fresh wounds do not provide a reliable picture of the bacterial flora so one must depend on cultures. Early information is essential particularly in the case of anaerobes, in order to institute treatment before the infection gets out of control. The patients whose wounds yielded anaerobes were carefully observed and the earliest signs of clinical infection detected. This information led to early amputation and probably saved the lives of several patients.

Aerobic organisms were cultured from 120 wounds, and in only 14 wounds were the cultures negative. The staphylococcus although frequent, usually remained localized. A case report of a serious committed localized. A case report of a serious committed localized.

plicating aerobic infection is presented

The value of local implantation of sulfanilamide in the effort to prevent and control infection is doubtful. The authors did qualitative chemical tests on serum from the wounds of patients or on macerated tissue removed at débridement and found that sulfa drugs were present in 60 83 per cent of the wounds from which are robes were cultured and in 57 ta per cent of the wounds from which anaer obest were cultured. Therefore the local use of sulfornamide certainly is not bacteriocidal. The value of the drug as a bacteriostatic agent is more difficult to evaluate.

The wounds of 2 patients from which the dostediam perfringens was cultured were constantly migated with azochloramid solution and sulfadia mae was given orally. One patient, in addition received due oou units of penicillim. In spite of this regimen for 9 days cultures of these wounds still Yaddet the clotridium perfringens, although neither patient developed gas gangrene. This would stress the fact that chemical sterilization of a wound is practically impossible. Rosert R Biochaw ALD

8mith Petersen, M. N. Larson, C. B., and Coch ran, W.: Local Chemnotherspy with Primary Closure of Septic Wounds by Means of Drain age and Irrigation Cannulae. J. Bene Surg. 1045, 27, 563.

This article deals with a method of treating septic wounds, whereby the largest part of the wound is closed and cannulae are inserted through the superfacial structures down to the septic process. Dakin solution has been used actensively and even now its often substituted temporarily for other chemothera peutic agents. Silver pectunate solution has been used in a limited number of cases

Penncillin has been used for the last year. The tenncillin has been used for the last year. The tenning consists of primary closure of the wound around the canulae gauze sponges being packed between the skin and the flange. The dressings stabilize the canualae, A number of cubic centimeters of penicillin are delivered from the supply

bottle into the wound through the inlet cannula. The outlet cannula is left open until the clear fluid appears, then it is clamped off

Penicillin is delivered into the wound every 4 hours. The strength of the solution is 450 units per cubic centimeter. The period of administration varies from 2 to 4 weeks. Dressings are infrequent. The cannulae are removed under peniothal aines thesis and the soft tissue defects are closed leaving only a small rubber eathert in place for the administration of penicillin for a few more days. Systemic chemotherapy is used in conjunction with the local chemotherapy. The usual dosage is 100 000 units for 24 hours. Four cases are reported.

CASE 1 A boy 13 years of age had recurring osteomychtis of the left fibula. The suggested technique was followed and the wound healed com

pletely in one month

CASE 2 A man 24 years of age had recurring symptoms referable to his right ilia. Roentgenograms showed changes characteristic of cateomycli its. Operation consisted in acquestrectomy saucen zation and insertion of glass cannulae. The wound healed completely in 5 weeks.

CASE 3 man 38 years of age had theumatoid arthrits with a righd spine and fibrous antlylosis of both hips in 1934 he had had a fascia late arthroplasty of the left hip with postoperative sepsis which had persisted for a period of 5 years. During a vitallium mold arthroplasty free pur was en countered in the line fossa and treated. There has been no recurrence of sepsis for 6 years.

CASE 4. \ man 19 years of age had multiple foct of osteomyehts occurring over a period of 7 years In July 1944 acute symptoms from a new focus in the mid-shaft of the right femur developed. Operation included saucerization and insertion of 2 vital lum cannulae with wound closure. Ten months have elapsed since operation and so far there has been no local recurrence of sepsis.

The authors state that this is not a perfected method with 100 per cent cures. There have been cases with local recurrence of sepsis but these have been relatively few.

A number of figures and roentgenograms showing the method in use are included

In the blood pressure, pulse, and respiratory rates are constant with whatever changes may result from the climination of the state of excitement Apomorphine hydrochloride is marketed in tablet

Apumupane nyurochorue is marketed in laise. form, and is subject to Federal regulation as a narcoinc, It is relatively untable and should be decoin. It is relatively unstable and about the decaded if a Secensia there is visible when it is diluted. The sectative of Appeoble action of the drug has had been considerated in constitution. little stress in most texts. Present clinical experience shows that subspectle amounts are free from the stores that superioric amounts are the store of described based of respiratory and chronisty collapse. The drug is readily absorbed from all micross studence put its action is more certain when given parenterally

The report is based on more than 500 administra tions for the therapy of emergence delichm. It was also used as premedication for emergency operations complicated by severe excitement and acute alcohol ism, delinum tremens and severe acitation ac companying morphia addiction. Another field of mediunes was for the marked muscular and psychic overactivity occasionally seen before operation after the hypodermic injection of acopolamine or atropine.

Six case reports were given in detail illustrating the types of cases which showed response to the drug It was not given as a substitute for other de pressant drugs except in the special circumstances mentioned. Experience with the drug was limited to sargical patients. There were no accidents or un toward effects

The dose vaned from 1 to 2 mgm for the average adult patient. It was dissolved in 10 c.c of sterile normal saline solution and administered intra venously. It was safe to repeat half the amount if sedation was inadequate after 20 minutes, and the entire initial dose could be repeated should the excitement reoccur after several hours.

The drug was contraindicated when either asphysia or oxygen want seemed to be the important factor in the excitement or debrium.

MARY KARP M.D

Koppanyi, T : Acetaidehyde a Volatile Ancethetic and Sympathetic Stimulant Anesthesiology 1945, 6 603.

This report concerns the effect of acetaldehyde when administered by inhalation. The product used for the study was freshly distilled from paralde byde in the presence of sulfuric acid and water and adult dogs were the subjects. An undiluted or so per cent aqueous solution of acetaldehyde was supplied by means of a cone or towel wrapped around the nostrils and mouth. Anesthesia was established within 5 minutes, the trachea cannulated and the common carrotoid artery exposed and cannulated for recording the blood pressures.

Recovery usually occurred within an hour and was uneventful. Toxic effects of an overdose in cluded profound cardiac slowing which was in part due to central vagus stimulation and idioventricular hythm. Conventional resuccitating measures were usually successful in saving the animals.

Preliminary medication of morphine or berbitu nits reduced the quantity of acetaldehyde needed for the anesthesia. The rate and depth of respiration were increased and there was a substantial rise of the blood pressure. There were sympathetic stimu lating actions of the drug in addition to the central description of the drug in addition to the central department action, for it produced all signs and symptoms of typical thoracolumbar autonomic excitation such as pupiliary dilatation relaxation of the decidenal muscles and dilation of the bronchial musculative.

The drug is a local irritant to the skin and mucous membranes, but this action is less than that of chloroforn. Its odor may be made less offensive by the addition of various volatile oils or ammonia

water Acetaldehyde ammonia is a pressor agent and a general sympathetic stimulant, while acetaldehyde sodium bisulfite is not. The inhalation of concentrated acetaldehyde vapora is likely to produce cardiac, vascular and respiratory toric effects. Maxy Karp M.D

Thornton H. L. and Rowbotham S. Anesthesia in a Maxillofacial Surgical Unit with the British Liberation Army Anatheniology 1945 6 580

This article is based on the problems encountered and the anesthesia method employed on 1637 patients with maxillodacial injuries as encountered by one maxillosurgical unit in England during World War 2. The types of injury usually found were classified into the blow-out injury, the through and through injury to the maxilla with disorganization of the nasial passages the retained foreign body in the tongue, the brawny neck, edema of the foliotis direct involvement of the glottis and laryny and injury involving soft tissue alone.

The premedication for the average case was omnopon (gram \$\foathernightarrow{1}\) and scopolamine (gram \$1/50) given subcutaneously 1 hour before or intravenously a few minutes before the operation. The nose was occanized just prior to the injection of anesthesia and the larynx under direct vision prior to passing a tracheal tube.

Induction presented the greatest problem in this type of anesthesia because of the difficulty of placing a mask on the face. The airway was often obstructed partially or completely and there was a tendency to laryngeal spasm. Anesthesia by inhala tion was found difficult and intravenous anesthesia was the obvious alternative. A 1 per cent solution of bromethyl (avertin) in 5 per cent glucose when given intravenously produced rapid anesthesia which was highly satisfactory for intubation. The solution was warmed to blood heat and tested with Congo red before use. No laryngeal spasm or strangling was observed in any of the cases and there was early relaxation of the law.

Intubation was safely effected in the early second stage. The dosage infused varied considerably but the average case was intubated on 300 c.c. There was no cause whatsoever for anxiety regarding the safety of the drug in the cases presented, with the exception of I case which was reported in detail Death may have been due to primary heart failure.

For intibation the nasal route was most commonly chosen and the procedure was carried out under direct vision in almost all cases. The endotracheal tubes used were plasticised polyvinvlehlorid (portex). The advantages of this type over the standard rubber type were the remarkable durability of the tubes, ease of sterilization freedom from kinking reduced irritability to the laryar which permitted the lightest possible anesthesis and the unusual property of the material which enabled it to be modified to individual requirements after it had been softened by bolling

	13	II	
40	12	10	

The technique is described in detail One and one half cubic centimeters of tetrapon (3% solution) (amiliar to pantopon) and 10 cgm of ephedinne were given subcutaneously before operation. The patient was piaced in a lateral decubitus position and spinal tap effected. The volume of percaine given was determined by means of the above table.

The solution was injected at the rate of 4 cc. per minute. The needle was left in place in the sub arachinoid space and after from 5 to 10 minutes the height of analgesia was tested. If the analgesia was too low a supplemental dose of from 3 to 6 cc. of percaine solution was administered the needle removed, and the patient turned on his back in a horizontal position or in a few degrees of the Trendelen burp position. Infusion was then initiated and evipal sodium in a to per cent solution was injected at approximately 1 cc. per minute. The sim as a rule was to keep the patient doxing. Saline solution was administrated to maintain patiency of the needle

In pr 2 per cent of the cases the effect of the combination of drugs was considered deal 8 2 per cent were considered to have a moderate effect and o 6 per cent had a poor effect. The effect was poorest in men in the age group between 30 and 49 years and in operations above the umbilious. In 4 cases the evipal produced a mild excitation.

The dose of percaine averaged 10.4 cc in men and 17 cc. in women in operations above the umbilicus and 16 cc. and 15 o cc., respectively in operations below the umbilicus. The largest dose was 32 cc. administered to a man of 37 years for gastrectomy. The average dose of evipal was 86 cc. Twenty three patients alori satisfactorily on 3 cc. 15 on

2 c.c. and r patient even on s.c.. Complications arising from the combination were lew. The blood pressure in most cases remained constant in apite of immted usage of the Trendelen burg position. Eighth-seven per cent of the cases showed a partial fall which did not exceed 30 per cent ro.8 per cent exhibited a fall between 31 and 50 per cent and 23 per cent exhibited hypotension of over so per cent. In most cases no changes were demonstrable in the respiration and the pulse also remained unchanged. Vomiting occurred more rarely than in spinal anesthesia alone. Headache was present infrequently.

In 15 6 per cent of the cases the postoperative retention of urme exceeded 24 hours. This high percentage was considered possibly due to the wide use of morphine medication. There were 4 deaths during the first 24 hours but in no case was anesthesia con sidered a factor. One death which is perhaps ascribable to the combination anesthesia occurred before the operation was completed.

Parathesia occurred in 1 patient on the soventh day after operation it was localized to the radial side of the right thumb Pneumonia was a post operative complication in 4 cases 3 of which had a fatal outcome on the seventh ninth and eleventh days respectively

The drawbacks to the method include the some what long preparation the need for an expenenced anesthetist besides a nurse at the head of the patient and the possibility of unlateral anesthesia

The method was contraindicated in liver damage abock conditions and severe morbus cordis sepsis tuberculosis and syphilis Mary Kare M D

#### Fairclough W A. Sixth Nerve Paralysis after Spinal Analgesis Brit M J 1945 2 801

The author briefly reviews the literature concerning the occurrence of sixth nerve paralysis following spinal analgesia, and reports that in a series of 2 our spinal anesthesias 10 instances of partial paralysis were noted. Of all cranial nerve palsies following spinal analgesia, abducens paralysis constitutes well over 90 per cent of those reported. The various theories which have been advanced to account for the vulnerability of the abducens nerve are listed and all of them attribute it to the purely anatomical disadvantages of this nerve

A new theory is then suggested as to the possible cause for the frequent paralysis seen in this nerve The factors necessary in binocular stereoscopic single vision are listed and the frequency of some disturbing factor in this complex mechanism is mentioned Phylogenetically binocular vision is a recently acquired sense and presumably the first lost. The early occurrence of diplopus in unpremedicated inhalation anesthersa and in inchriation is mentioned as an example of the upsetting by a toxic substance of the normal physiological balance necessary for binocular single vision. It is pointed out that the normal power of adduction of the two eves is three times as strong as the power of abduction Lsophona is a common form of muscle imbalance. The loss of a part of the tonic impulses conveyed by the abducens nerve could then easily upset the balance and make manifest a squint that had been latent until the introduction of the spinal anesthetic. To explain why most such pareses are unilateral the author states that when the effort to maintain binocular vision is abandoned the second eve is often able to carry on monocular movements normally with the less powerful stimulus being transmitted over the abducens nerve

Ten cases of partial transient unilateral paralysis of the abducens nerve following spinal analgena (spinal percanne 1/200—from 15 to 3 c.c.) are reported with brief abstracts. Nine of the patients examined after their vision was subjectively normal had an exophona varying from 1 to 5 l D at 6

meters and none had exophoria. The diplopia appeared in from 5 to 11 days after anesthesia and pensited from 2 weeks to 14 months. Covering the affected eye gives relief but is not advised as the removal of the atimulus toward fusion and the redevelopment of binocular vision is thought to retard recovery. Dark glasses with a covering over the outer third of the glass covering the affected eye are recommended. Muscle exercises and fusion training may be found necessary in those cases in which a natural recovery is delayed.

THOMAS DODOLASS, M.D.

Engatrand, L. and Friberg, O : On the Function of the Liver as Affected by Various Operations and Anosthetics. Acts, chir scand 1045 on 5

The liver function was studied portoperatively by means of a series of tests of hippuric acid synthesis (intravenue test) in association with a number of different operations and forms of anesthesis. There was a considerable dissertation on the physiology of the liver and the methods available for the study of

its function.

The first group of experiments was made on cases subjected to high spinal anesthesis. It was shown that there was a reduction in the liver function in those cases of high spinal anesthesis (with persine) in which a fall in the blood pressure occurred. The cause was considered to be an anozemic injury to the liver.

No reduction of liver function was found with inhalation narcosis with ether a fairly great reduction was observed penisting in most cases for more than a week after the operation. In abdominal operations ther narcosis slways appeared to reduce the liver function even when there was a high glycogen content in the liver during the narcoss and when an adequate supply of oxygen was given during the anesthetic.

The reduction of the hippoints acid synthesis varied according to the magnitude of the operation. Cyclopropane was the anesthetic which was least humful to the liver even in cases showing a strong reduced liver function preparentively.

When narcotal nitrogen-monoxide (nitrous oxide)
was used with from 15 to so per cent oxygen or less
a decrease in the liver function test was maillest,
but none appeared when the oxygen administration

Was 10 per cent or over Preoperative and postoperative management with respect to the liver was discussed and the hippuric acid test evaluated. In the cases with strongly reduced liver function it was found important to treat the liver preoperatively for from five to seven days with carbohydrates and proteins, fats being excluded from the food glucose was then given subcutane ously on the morning of the operating day Cyclopropene was considered the anesthetic of choice and an abundant supply of oxygen was continued throughout the operation. Postoperatively a glucose drip was retained for from 4 to 6 days and plasma transfersion was administered in the cases with disturbances of the serum protein content. From the third postoperative day on, fat was included in the food along with a high carbohydrate diet. Although cyclopropane was the agent of choice in these cases, local anesthesia plus narcotol nitrogen monoride oxygen could be employed if adequate oxygen was administered throughout, but ether was definitely MARY KARP M.D. contraindicated.

Curtis, G. M., and Fertman, M. B : Blood Jodine Studies. Ann. Surg 1045

This paper is one of a series of reports on funda mental metabolic studies. The relation of the hasal metabolic rate to the blood iodine in a large variety

of thyroid diseases was investigated.

The authors conclude that the basel metabolic rate is a more reliable test of thyroid activity than is the estimation of the level of the unfractionated whole blood iodine. However they state that both determinations, considered together are superior to either one alone.

Although the basal metabolic rate is elevated in all forms of toxic golter, it is increased more in exophthalmic golter than in any other form of golter with hyperthyroidism despite a similarity in the extent of increase of the average infractionated whole blood iodine in all forms of toxic goiter

Schafer P W t The Etiology and Treatment of Polycythemia Rubra Vera Ann. Savg 1045

By means of proprioceptor depressor neurotomy a form of absolute polycythemia has been produced experimentally in dogs. This form of experimental polycythemia disappeared following extensive para vertebral sympathectomy Support is thus given to the theory that the normal, and some abnormal formation of red blood cells by the bone marrow is under the control of the sympathetic nervous system through its regulation of the caliber of the presinusoidal vessels of the marrow

The theory is advanced that some cases of poly cythemia rubra vers in man are due to constriction of the presingsoidal blood vessels of the bone mar row and extensive paravertebral sympathectomy is proposed as treatment for this disease. The suc cessful result of treatment of 1 man with polycy themla rubra vera by extensive paravertebral sympathectomy is then reported. SAMUEL KARW M.D.

Tyson, M. C., Vogel, P. and Rosenthal, N 1 The Value of Penicillin in the Treatment of Angranulocytosis Caused by Thiourscil. Bleef 1 Hemet., 1946 1 53

Since 1043 when Atwood found that thiogracil effectively inhibited the function of the thyroid gland, this drug has come into increasing favor in the clinical treatment of hyperthyroldism. In severe hyperthyroidism this agent reduces the basal metabolic rate and brings about clinical improvement. Of all the thyrold depressing drugs thus far tested thiournal seems to be the least toxic. However, sufficient cases have been reported to demonstrate convincingly that thiouracil may affect the bone marrow in such a manner as to induce a severe or even fatal agranulocytosis. During his preliminary experiments. Atwood noted 1 natient who had been given a relatively large dose of thionraell and developed agranulocytods. This complication has been observed with varying frequency in later sense of

The present authors believe that the use of thioursell is more dangerous than a survey of the litera ture would indicate, of 54 cases treated with the drug at Mount Sinai Hospital. New York, 6 (approx imately II per cent) developed agranulocytosis. Three additional cases of postthiouracil agranulocytoms came under the care of the authors. In spite of treatment, 4 of the o cases studied were fatal 5 patients recovered after penicillin therapy Since penicillin has no deleterious effect on the bone marrow, the authors believe that it is ideal for all cases of agranulocytosus and especially for those that may have resulted from chemotherapy with thiouracil, sulfonamide aminopyrine, or other drugs. This article calls attention to a number of import

ant concepts that may be summarized as follows 1 The cases that developed agranulocytosis had received thiouracil for at least 5 to 6 weeks before

symptoms of the complication appeared.

s In the treatment of agranulocytosis, penicillin is apparently effective in so far as it combats the bacterial invasion and toxemia, and enables the pa tient to survive until the bone marrow has regenera ted.

3 In attempting to explain why some patients de velop sensitivity to the drug and others do not, it is suggested that the cumulative effect of the drug may cause sensitivity and subsequent toxic action on the

myeloid elements of the bone marrow

4. While there is no question that under certain conditions thioursell is an excellent drug to tide a pa tient over an acute episode of thyrotoxicosis, and especially in preparation for thyroidectomy its effectiveness is present only during its administra tion. It cannot be considered as a medical cure, since it does not affect the basic difficulty of thyrotovicosis."

5- One can predict that in the future there will 5. One can predict that if the interest which be an increasing number of cases of agrandocytosis since additional courses of the drug will be given as recurrence lakes place and there will thus be an opportunity for more patients to be sensitized to the drug For this reason it would seem advisable at uture area the use of the drug only to selected present to limit the use of the drug only to selected properative cases and those in which operation is contraindicated

## The Surgical Problem of Cancer tomas within this time in the Lymph Nodes. Sergery 1945 18 608. Sugarbaker E.D

This article deals with the problem of the treat ment of cancer in the lymph nodes in an attempt to determine how such treatment may be developed to marimum advantage. Considerable divergence of opinion prevails concerning the ideal plan of treat ment of occult cancer in the lymph nodes. Thera pentic dissection conveys the idea that the size and character of the nodes indicates lymph node involvement. Prophylactic disaction implies that the nodes are suspected of containing cardinoms cells despite the absence of physical aigns of node involvewelfare the ansence of physical signs of node involved ment. It is apparent that in both instances errors that in soft ment will occur There is a wide variation in the terror of the te the frequency with which different tumors metastakize to the lymph nodes Different sites of pri mary involvement and quantitative differences in the lymphatic systems of the parts, the size of the lesion, whether the tumor is primary or recurrent, the nature of previous treatment, and the duration of symptoms must all be taken into consideration. The node incidence in some of the commoner tumors

Another consideration not discussed in the litera the but which seems to be pertinent to the problem is given in Table I relates to quantitative node involvement in dissection specimens from the various tumors and the

relative frequency with which widespread metastases occur. A table showing the average number of nodes involved for different types of cases and the per centage of cases with more than one node involved able that if a given tumor metastasizes with regu is presented in the original article. ance that it is given tumor inclusionaixes with resultantity to only one or two nodes, remains confined there after all clinical doubt as to its presence has there after all clinical doubt as to its presence has been dispelled and very farely kills by reason of been dispelled and very farely kills by reason of been overly farely kills by reason as the control of the such a tunor more such as the control of the such as the such night as well be treated by a dissection done thera petitically instead of prophylactically Conversely, pourceasy unices of prophysicically to the local nodes before its presence becomes dialog. nodes before its presence becomes clinically apparent, is found to involve numerous nodes of the specimens examined and not infrequently brings about death examineu ann nor inirequently brings about death by distant spread, dissection must be carried out prophylactically it it is to be of any use at all. Therefore it is someoned these the modules is Therefore it is apparent that the problem is con certed not only with how frequently regional nodes cemen not only when now requestly the disease is are involved but also with how rapidly the disease is are involved out also with now rapinity the disease is apt to spread beyond the limits of the removable chain

In many instances the anatomy is so adaptable that removal of the primary tumor with the regional nodes becomes little more of a task than removal of nodes occumes intue more of a rask inan removal of the primary tumor alone. This is true of the stomach, bored, and lungs. The question of node dissection therefore pertains mainly to those tumors in which the primary and node area are best treated sepa rately either at one sitting or in stages. Considera tion must be given to the relative value of the several major dissections - cervical axillary and inguinalbased on the anatomy peculiar to each and the way they lend themselves to node dissection. One must uney remu mensueves to some unsecured. One must also consider the added risk of prophylactic node also consider the added risk of prophylactic node also consider the added risk of prophylactic node. dissection in poor risk patients in the cancer age

In the surgery of cancer there are in general, two in the surgery of cancer there are in general, which major problems (1) the degree of radicalty required major problems and (2) the degree of radicalty which by the tumor and (3) the degree of radicalty which the major and deleters of the control of the case the patient will withstand. Overestimation of the first and underestimation of the second will result in too high a percentage of postoperative fatalities. The c n terse will result in too low a percentage of cured ca co Contraindications to therapeutic and proj hylactic node di section are presented as well as the arguments for and arginst prophylactic dissection in cancer of the I p JOHN L. LINDOCEST M.D.

# GENERAL BACTERIAL, PROTOZOAN AND

## PARASITIC INFECTIONS Pridemiology Unit Number 22 Sulfadiazine Prophylazis and Resistant Streptococci J Am II

A previous article has described the pronounced reduction of streptococcic disease which occurred at a large naval training center in the Northwest as th result of sulfadiazine prophylaxis The present report deals with the loss of effectiveness of this prophylaxis due to the appearance of sulfadiazine

Viter approximately 3 months of successful sulfa re utant strains diazin prophylaxis of respiratory infections at a large naval training center the effects eners of this m a ure became progressively less and e entually a major epidemic of streptococcie duease occurred

An increase in dorage to as high as a gm. daily d I not prevent streptococcic diseases and it was the impression of medical officers at the center that the drug had lost its value therapeutically in these

The loss of prophylactic alue of sulfadiarine wa originally associated with an absolute and relative increase in the frequency of group, 1 type 10 in fects as to the practical exclusion of all other types. Later group A type 17 became relatively frequent. These two types were shown by laborat 1) methods

to be sulfonamide resistant in vitro Other types I streptococca with a few exceptions

of type 3 were not sulfonamide resistant The proportion of sulfadiazine resistant strains

was greater in those recruit camps getting sulfadiazine prophyla ; than in those not getting sulfa

There was som suggestive evidence but no defi aite proof that a the presence of sulfadiazine re istant strains sulfadiazine prophylaxis tended to nerease the strept scoccic infections particularly scarlet fever

The results of these suggested and drug actions. The results of these suggested that under the influence of certain stimuli a reaction that under the inhumence of certain summin a reaction took place involving the pituliary the advantage tex and the spleen. The question then was whether took place involving the pitting of the agreement core and the spleen. The question then was whether the spleen played its part by releasing the active substance or by causing some other reaction. A crude extract of guines pig spleen in saline solution Mas bichaicq and injected subcutaneously in order to study its effect on the bleeding time of guines The mode of action of the spleen was studied pies and found to have the following effects (1) it re duced the bleeding time (a) it increased the capil lary reassance and (5) it inhibited the histamine release from the blood cells. The author summarizes his observations and concludes as follows

in the course of a study of the pitultary adrenal reaction to stress this response was found to be in hibited by splenectomy It was also observed that spleen extracts contain an active substance which can reproduce the reaction to the original stimulus This active substance was isolated and obtained in and active aurosence was movated and voicemen in pure crystalline form. It is probably part of the bute craverance system which protects proteins against trypsin The sphen as an endocrine organ may therefore play a part in the control of protein me labolism and its adjustment to conditions of stress.

# SURGICAL PATHOLOGY AND DIAGNOSIS

Bowden R. E. M. and Gutmann E. The Clinical Value of Muscle Blopsies. Lancet Lond 1945

The authors note that there are several medical and surgical conditions in which examination of buonsy specimens of muscle is helpful or even es sential in the establishment of a diagnosis but until recently this method has been largely neglected in the investigation of neuromuscular disorders certain cases of paralysis associated with vascular lesions, the value of muscle biopsies was demon arrated In peripheral nerve injuries they have yielded information which has been of great as 1st ance in diagnosis prognosis, and treatment. In northypus of gradual onset it may sometimes be difficult to determine whether the lesion is primarily neurogenic or myogenic and in such cases even electrical reactions and electromyography some times do not give decisive information Bealdes Elv ing information about the state of the muscle fibers a muscle biops) is a form of nerve biopsy in that a museue outpay is a torin of nerve index in con-nerve fibers empty. Schwann tubes or motor end plates are almost always found among the muscle

The authors state that the purpose of this article is to indicate the value of muscle biopses in the diagnosis, prognosis, and treatment of neuromuscu pbers lar disorders. Four types of cases have been investi gated (1) lower motor neurone lesions due to pen pheral nerve injunes (2) lower motor neurone exions other than peripheral nerve injuries, (3) pri mary muscular disorders and (4) vascular lesione,

Some illustrative cases are described and summaries given of the indications for performing biopsies the methods of treating specimens and the findings.

The indications for performing a muscle biops)

# A DISCUSSION OF CONTROVERSIAL POINTS IN AMPUTATION SURGERY

# FRANCIS M MckEEVER M.D. Battle Creek, Michigan

THERE is great difference of opinion between surgeons concerning the various procedures of amputation Some disagree concerning only minor variations in technique or un important matters of personal preference others differ in matters of basic importance In time of war because amputation is fre quently necessary after severe injuries from high velocity missiles great experience is

At Percy Jones General Hospital in the 33 gained in this field of surgery month period from January 1943 to October 1945 the amputation service has cared for 2 783 patients with major amputations This is a greater number of amputees than was cared for by the entire Medical Department of the United States Army during World War I which produced only 2 635 amputees These 2 783 patients had a total of 2 988 am putated extremities. The incidence of ampu tation per patient and the location of the extremities which were lost are presented in

As a result of this experience many procedures and techniques of amputation surgery Table I which are controversial have been observed Observation of this group of patients has established that certain methods have a defi nite value while others give less favorable results.

OPEN CIRCULAR AMPUTATION

In the United States Army Medical Corps the open circular amputation or as it is more commonly and less accurately termed guillotine amputation was mandatory in all instances of amputation for trauma in forward installations In this type open operation the skin is cut circularly at the lowest level of good tissue and allowed to retract. The fascia is then incised at the line of skin retraction and the superficial muscles are sectioned and allowed to retract The deeper muscles are then sectioned at the line of retraction of the superficial muscles and allowed to retract. The bone is then cut through at the line of nuscle retraction The leg is not chopped off as if by a clearer Thus procedure carried out TABLE 1 —AMPUTATIONS IN 2783 PATIENTS

correctly produces a potentially inverted cone when traction is applied to the skin but leaves no flaps to trap infection. If the patient is given proper postoperative care the essential of which is traction the stump is usually ready for definitive surgery in 8 weeks. If constant traction is not applied muscles retract and a large section of bone protrudes from the end of the stump (Figs. 1 to 4).

The flap type of open operation in which overhanging duck bill flaps are produced was forbidden in the American Army forward hospitals. The British Army permitted its surgeons to do the so called flap guillotine operation as they deemed it advisable. Many American surgeons both in military and civilian practice have taken exception to the absolute deletion of the flap type operation in forward hospitals and there has been con siderable heated debate around this point. It was claimed that it was out of the question to keep traction on the open circular amputation. and that stumps resulting from this type of open operation would arrive in poor condition in the Zone of the Interior This objection was not valid. In 3 years and in 2 783 pa tients with 2 988 stumps there were 30 stumps, or 1 per cent, which had not had the proper postoperative care by the time they arrived at this Midwestern hospital Many of these patients arrived at the Zone of Interior hospital with effective traction still on the stump having crossed half of Europe the Atlantic or Pacific Ocean and half of this country with very ingenious combinations of adhesive tape plaster and elastic bands to keep the skin from retracting

The only valid arguments for the flap type of open operation are (1) time, (2) the avoid ance of a second operation. The argument of time is valid in that if the immediate convolvescence is not complicated by severe sepsis, early secondary closure is possible. In some instances after the first 10 days to 2 weeks the flaps can be permitted to fall together and be loosely sutured thus obtaining a closed stump soon after the injury. The second point is not a valid argument in very many instances. A high percentage of amputation stumps resulting from the secondary closure of inaccurately cut flaps will be poor stumps, with

too much redundant skin and muscle at their ends. This condition will require a late secondary operative procedure to produce the ideal stump. A young vigorous man is going to and must, use his prosthesis hard. He cannot get by with a poorly teilored stump. For the aged individual who will probably use a prosthesis very occasionally and in whom the avoidance of surgical incidents is desirable, the flap type open operation may have added ment. For the young in whom perfection of stump is desired the open circular amputation is believed superior as in this method a late definitive operation is an accepted fact.

In amputations done for trauma, the danger of ever present infection becoming invasive and virulent is reduced to an absolute minimum by the perfect drainage afforded by the open circular operation. The definitive surgery to complete the closure of an open circular amputation is in effect a late sec ondary wound closure. Whether it be accomplished by plastic closure or by reamputation at site of election it is associated with very little danger. In carrying out the definitive or final operation in 2 088 stumps in 2 783 patients who had had an open circular amputation a severe recrudescence of infection in the amputated extremity as manifested by cellulitis abscess, high febrile reaction and general sepsis, occurred in only 20 instances, or o 66 per cent. No patient died as a result of the definitive surgery on the guillotine stump.

Five per cent of patients had some complication of their final surgery. The common complications were a mildly infected hematoms in the stump without systemic reaction or a marginal skin necrosis which required a minor skin plastic later. Most of the patients with the complication of hematoma on its evacuation after the removal of a few stitches recovered with a satisfactory stump and without further surgers.

The severe infections resulting from secondary closure or reamputation occurred many times where they were least anticipated Some were in a stump which had been conpletely headed for many months or had been covered by a skin graft for many months. Other stumps which had more than a reason able amount of granulation tissue at their

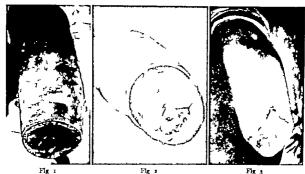

Fig 1 Fig 2 Fig 5 Fig 1 Open circular amputation, immediately post operative.

Fig a. Open circular below knee amputation 8 weeks postoperative. Turned back stockmette is for skin traction. As result of continuous traction, this stump is now ready

end at the time of surgical revision convalesced with no reaction. The only inference to draw from this is that regardless of how nearly normal the condition of previously infected tissues may appear it is never free of bacteria and those bacteria may become rampant at any time.

All patients received for 48 hours prior to surgery either sulfonamides or penicillin systemically They also received one or the other of these antibiotics for as long post operatively as was indicated by their general condition or the local condition of the opera tive site. Sulfadiazine was the sulfonamide used About 1 800 patients received sulfadia zine and 1000 penicillin. The patients pre ferred sulfadiazine to escape being punctured with a needle One seemed about as effective as the other in this type of surgery and a positive stand for either to the exclusion of the other was impossible. One or the other how ever should be used In 500 operations sulfonamides were used topically in the stump Late in 1943 the topical use of sulfa nilamides was discontinued Since discon continuing the topical use of sulfonamides, the stumps healed better with less reaction and less hematoma.

Fig. 3

f. intel operation. Skin is pulled well down over end of stump which is healed by soar contracture.

Fig. 3 Below knee atump which has not had traction postoperatively. Skin has retracted and 5 centimeters of bone protrudes, which will have to be sacrificed.

#### TECHNIQUE OF AMPUTATION

Opinion differs greatly regarding the actual technical steps of performing an amputation As one reads surgical treatises on this subject

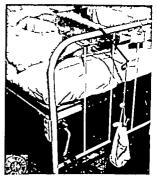

Fig 4. Method of applying skin traction to open circular amputation. The stockinette is glued to the skin before patient leaves the operating table and traction is started immediately.

Fig. 5. a, left, Anteroposterior view b, Lateral view Good tapered below knee stump. Skin, nonadherent no bulbous muscle over end to bony prominences no super field neuromes.

the impression cannot be escaped that much has been carried through the years from book to book which does not hold in the light of present physiological and pathological fact.

The surgical technique of amputation should aim to produce a stump which has soft flexible nonadherent skin and which has no redundant muscle. There should result no projecting bony prominences and the neuromas of all nerves should be well covered and not subject to pressure.

In order to avoid adherent skin dissection of the skin flap in the subcutaneous plane must be avoided as much as possible. A certain amount of freeing of the skin to effect a smooth closure is necessary but this rarely needs to exceed 3 centimeters from the skin flap is distallent As nearly as possible the skin should be left attached to the factor.

Wherever possible fascia should be closed over the bone end. In many instances of secondary closure this is impossible. Either fascia and skin or skin alone should be the only covering of the bone end Muscle should never be used to cover the bone end as it results in a redundant unattached sliding mass at the end of the stump which shrinks very slowly and ultimately turns to scarred avascular tusue. All muscle should be coned out at least perpendicular to the bone end and pref erably with its periphery slightly proximal to the bone end. Even in the avascular stump the presence of excess muscle in no way aids the skin circulation, as there are no perforating arteries between muscle and skin

Some controversy exists relative to the treatment of the bone end Apenosteal technique has for years been advocated. By this is meant the removal of a cuff of perioteum about the periphery of the end of the bone The cuff is variously recommended to be a quarter to one half inch in width. This procedure does not seem a logical one as it deprives the underlying bone of a certain amount of blood supply In the presence of any sepsus it will in a high percentage of patients, result in a ring sequestrum. The procedure is therefore contraindicated in any secondary closure or secondary reamputation. or in any patient in whom there is any chance of an infected hematoms. Even in the absence of all infection in some instances a ring sequestrum will form because of the avascular necrosis of the bone end, which has been denrived of permsteum.

The periosteum should be incused cleanly at the saw line and at the completion of the box section the periosteum should be adherent to the end of the bone about its entire dreumference. The only reason for the removal of any periosteum from the bone end is that the handling of this membrane has been faulty and rough, thus necessitating the removal of

tags stripped loose

Hemostasis is of utmost importance to the end result of an amoutation. Time should be spent tying all small muscle bleeders indi-The development of a moderate vidually hematoma may delay recovery many weeks and even necessitate further surgery avoid the collection of blood even after careful hemostasis, it is well to drain the stump with a small rubber drain for 48 hours. Many amputations are done under spinal anesthesia, and a reduced blood pressure may lead the surgeon to a false evaluation of bemostasis. It is well to know the patient s arterial tension before the wound is closed and if it is 20 to 30 millimeters below his preoperative pressure, to have it raised to normal by an injection of ephedrine before the flaps are closed. This will often make what appeared a dry field bleed profusely

No point in surgical technique has caused as much debate as the method of treatment of the nerve end. This debate has undoubtedly

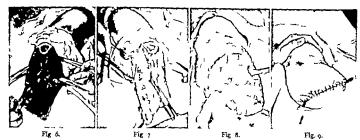

Fig. 6. Technique of below knee amputation, skin not lifted off fascia, tibia tapered with periosteum adherent to end, nerves cut high in fascial plane

Fig. 7 Technique of below knee amputation, muscle coned out so that only fascia and skin remain to go ove bone end.

resulted from the distressing sequela of 'phan tom limb Many chemicals have been advocated for injection into the nerve to prevent neuromas. The time honored method of alcohol injection has had a long period of usage. British authorities have in recent years advocated the use of formalin as a neurotoxic injection. A Russian school has advocated the cauterization of the artery of the nerve proximal to its distal end. Duck bill closures have been described. More recently a method of burying the nerve end in the medullary canal of the bone was described (Firs. 6 to o)

It is well established that there is no chemical which will prevent the end of the cut nerve from healing by neuroma formation. I am unable to comment on the Russian method of depriving the tip end of the nerve of blood supply but believe it only places the neuromal more proximally. The recently advised method of burying the nerve ends in the medullary canal of the bone is open to great objection if the nerve crosses a joint in the stump as it could easily lead to a nerve put under traction in many motions of the extremity.

For the past 3 years in the Amputation Service at Percy Jones Hospital none of these methods has been used. In fact little or nothing has been done to the nerves in an amputation stump except to treat them with

Fig 8 Technique of below knee amputation. Fascia closed over end, drain placed beneath fascia excess skin is removed so that in actual closure, very little skin is separated from fascial layer

Fig 0. Technique of below knee amputation. Skin closed without redundancy Drain in angle of skin closure

respect and to hide their ends. The nerve should not be forcefully stretched so that it can be cut off high and then allowed to re tract so that it will return to its normal length rather the nerve trunk should be dissected and cut off high so that the neurona which will nevitably result in the natural healing of the nerve end is well recessed in muscle. If a large bleeding vessel is present in the nerve this should be heated.

#### PHANTOM LIMB SYNDROME

In 2 988 amputations there have occurred 15 neuromas which required surgical removal and these could probably have been avoided had the surgeon been a little more thorough in the original operation. The only indication for the surgical removal of a neuroma is a superficial location which would cause it to be subjected to pressure thus producing pain. This pressure may come either from the prosthesis or as a result of the bare stump resting on or striking a hard surface and can be demonstrated by palpating and tapping the neuroma, which will produce a shock like sensation moval of neuromas for the treatment of any phase of the 'painful phantom limb syn drome will result in failure

In this group of 2 783 patients 4 instances of painful phantom limb syndrome have occurred Undoubtedly more instances of this distressing complication will occur in this group of patients as the years go on A certain degree of phantom limb sensation seems to be almost physiological and this fact should be appreciated

Every individual with an amputation has a phantom limb Rarely does an individual with an amputation have a 'painful phantom limb This phantom sensation has a fairly uniform life history. It is present as a complaint in the days immediately following amputation and is usually more severe when the amputation has resulted from crushing trauma or is accompanied by great suppure

As healing progresses and inflammation and induration recede the patient complains less of the phantom pain. He will tell you that he has the foot or hand but that it does not bother him. After the phantom has lessened and the patient has learned to live with it, any surgical procedure on the stump will aggravate the phantom phenomenon temporarily. This fact is true even though the surgical procedure in no way involves the nerve end. In many instances a simple excision of a skin scar in this group of patients resulted in an exacerbation of phantom pains. As healing again ensued the disagreeable aspect of the phantom subsided

When the patient puts on a prosthesis and uses it successfully the phantom phenomenon rapidly assumes a less prominent place in his scheme of life. In fact many patients will proffer the information that the phantom is a help to them. It gives them some inkling of where their foot or hand is and what position it is assuming. This is the ordinary history of

the phantom phenomenon
The rare individual with the abnormal per
sistent painful phantom limb must be
distinguished from the common group who
have the normal residual. Although rure this
type of patient is not hard to distinguish.
Many times the distinction can be made by
the patient's scars. Too often such a patient
presents scars of removal of neuromas and
section of nerve trunks at various levels in the
stump. At the base of the extremity the scar
of a sunglical attack on the sympathetic.

nervous system may be present. In addition to these scars he may also present the pig mented marks of the morphine needle. The cure of a truly painful phantom limb by any surgery is extremely dublous. Certailly there is no basis for excession of neuromas or penheral nerve section in the treatment of this complication of amputation and sympathetic interruption does not have any great number of successes to recommend it. Whether the newly advised operations attacking the cre-ball cortex will now of value is not known.

bral cortex will prove of value is not known. Probably the only successful treatment of this problem is its prevention. Unfortunately this cannot always be done by the surgeon as it is impossible for him to control the environment of his patients. However in the early management of an amoutee he can use nar cotics judiciously and take all surgical mea sures to reduce and shorten extensive suppuration and tissue necrosis. It is almost universal that the picture of painful phantom limb is associated with the use of morphine or alcohol and with the poor adjustment of an individual to his environment. No surgery devised to date offers a cure for these un fortunates.

The following case history is illustrative of the complex nature of these patients.

A paratrooper lost his right arm in combat. He was a wary little individual who had a great record for valor. His arm was knocked off by an 88 millimeter shell and a companion applied a tourniquet. Following this he continued in combat for the next few hours until he was wounded in the thigh

On admession to a bosp tall in the United States be was cheerful, hard to keep track of and was all over the building. He had no complaints about his arm the always seemed to enjoy talking about combat and his personal emploits. His amputation stump was revised and he was fitted with an artificial limb, which he used with great deviently depute a very short tump.

After using his prosthesis for about 6 weeks he announced that he was returning to duty with the paratroops. This was most onusual but it seemed that while on vacation from the hospital he had good to a paratroop base where he contacted some commanding officer who saked for his return to duty While on this leave he had also made some joings

Two months after leaving the hosp tal for duty be returned complaining b therity and constantly that the fingers of his hand were clenched o the raim and that the nafts were cutting the flesh and burning life fire he could not sleep and paced the floor the

typical picture of the painful phantom limb syndrome

On questioning this patient about the onset of the trouble he related the following story After going to duty he did well and had no trouble. He had joined a paratroop battalion. After training with them he had finally talked his superior officers into ending him overseas again with the combatants He arrived at the Port of Embarkation Here he was given a medical examination. The examining medical officer put his hand on the prosthesis and as he did so sand You can t go overseas with a wooden The patient amoutee said that at that instant he became infurnated that the fingers of his amputated extremity dug into the palm of the absent hand with excruciating pain and that if his arm had been his own he would have slugged the damn doctor This pain pattern had persisted since this disappointment

This patient insisted his pains were due to pai pable neuromas in the stump. At his insistence and with great skepticism these neuromas were removed His complaints continued unabated Then one day about 2 months after the removal of the neuromas out of clear sky he came to the Medical Officer in the ward with a telegram in his hand and announced that he was cured. He stated emphatically that he had no discomfort in his stump and no phantom sensation. To demonstrate his recovery he waved his prosthesis around and lifted a table off the floor with it. It had been impossible prior to this to get the patient to wear the prosthesis. The telegram which he had received was an order from a relief organization for him to go overseas for duty with them in the Zone of Activity

This case history is well worth remember ing. It does not infer that knowledge concerning the painful phantom limb syn

drome is complete and that there may not come in the future some organic approach to this distressing problem. At present, how ever the painful phantom limb syndrome should be listed as a condition not relieved by surgical treatment. A careful analysis of all these patients will reveal one or all of the following factors to play a prominent rôle viz drugs alcohol or severe maladjustment and frustration.

#### SKIN GRAFTS IN AMPUTATIONS

There has been some advocacy of the use of split skin grafts to hasten healing of open amputations and also of the use of pedicle grafts to conserve length in a short stump No type of skin graft will stand the wear of a prosthesis and under no circumstances is even a pedicle graft a justifiable final procedure in the lower extremity. There may be rare in stances in the upper extremity in which a pedicle graft will preserve valuable length in the arm the wear and tear from the prosthesis is not so great and the circulation of the stump is usually superior to the lower extremity.

Split grafts have been advocated to produce early healing of open amputations and shorten the time of invalidism. Split grafts can be successfully applied early to open amputation stumps. However, if these stumps are given the proper postoperative attention by keeping

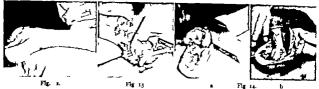

Fig. Skin incision for Syme amputation. Fig. 3. Discriticulating ankle from inside out in Symamputation. The oscale is being shelled out subperioste. By to prevent damage to blood supply of heel fign.

Fig. 14. Syme amputation. Section of tible and fibria centimeter provincal to articular surface of tible. Section at this low level proserves flare of ankle joint a, Saw is cut b, Articular surface being removed.

traction applied a split graft is not necessary The use of split skin grafts to produce early healing does not make the final surrery for an open amputation easier but more difficult. The normal skin rather than coming over the end, as it does with traction recedes to the margin of the skin graft. Consequently when the final surgery is done there is a paucity of normal skin and the result is that useful bone length must be sacrificed. If a severely trau matized or burned extremity has extensive skin loss and there is much loss of plasma early grafting may be the only means of restoring protein balance. Skin grafting of stumps for other than this reason is rather useless surgery If for any reason skin grafts are to be used the donor site should not be any place on the extremity which is expected to use a proathesis as too often painful irritable keloids result at the donor site which inter fere with the wearing of a prosthesis.

#### END-BEARING STUMPS

There is considerable disagreement in opinion regarding the ideal Inigh stump. These differences of opinion are almost on the basis of nationalism. The British take the stand that no amputation stump is suitable for bearing weight on its end, and that end bearing stumps will not stand up over a long period of time. They fit all lower limb prostheses even for a below the knee amputation so that weight is borne on the ischall tuber out?

The general consensus of American sur geons is that an end-bearing thigh stump is the best thigh stump possible Certam Canadian surgeons are staument advocates of end bearing stumps and are great enthusiasts about the Gritti Stokes thigh amputation in which the patella is attached to the sectioned femur for the weight bearing end. They are also great champions of the Syms amputation, an end bearing tibal stump. The British quite stalwartly condemn both the Gritti Stokes and the Syms amputation.

Our experience makes us feel that an end bearing thigh stump is the desirable type of thigh amputation to obtain when possible in an individual under forty. We have seen this type stump stand up under the most vigorous usage that can be given them and we feel that the patient walks with a more secure and better gait. We are not greatly enthusiastic about the Gritti Stokes type of end-bearing stump The reason for this is that despite the best of technique in carrying out the operation the patella will in a certain number of instances, slide off the end of the femur resulting in an unsatisfactory stump. Its scope of application is also very restricted. Where there is any chance of even the mildest sepsis, complications are likely to be very time consuming It is an osteoplastic operation, which to be successful requires the patella to unite by bone to the end of the femur just as any fracture heals. Even a mild infection may result in a failure of umon of the patella to the femur or in an osteomyelitis of both the patella and femur Because of potentially infected tissue the Gritti-Stokes type of amputation is not often applicable to the re-

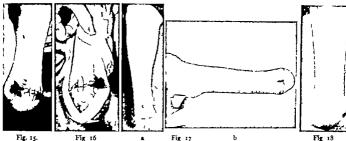

Fig. 15. Syme stump closed, drain in angle of incision for 72 hours.

Fig 16 Syme amputation. Cruciate straps of sterile flamed glued to skin, immediately postoperative to prevent displacement of heel pad from center of stump

amputation or closure of open amputations that have been done for trauma. In addition the tendoplastic type of end bearing thigh stump in which the patella is removed and the quadriceps tendon turned over the end of the femur produces an end bearing thigh stump which is just as good as the Gritti Stokes stump (Figs 10 and 11)

The Syme amputation has never been very popular in this country. It has had a lukewarm reception for the following reasons. Until the last few years it has been difficult to obtain a satisfactory prosthesis for this stump and American leg makers were not interested in supplying one. The Canadian limb makers have developed an excellent prosthesis for the Syme stump which is now universally available in the United States. Being unfamiliar with this operation. American surgeons have had too many failures due to necrosis of the sain flaps and to a misalignment of the heel pad

The operative technique and the post operative care of this stump are more exacting than in any type of amputation. The blood supply of the heel flap comes almost completely from the medial side through a branch of the posterior tibidi artery. If the operation is done from the inside out by disarticulating the ankle through the anterior portion of the incision and the os calcus is removed sub

Fig. 17 Good Syme stump. Weight bearing heel pad is centered under tibus, with neither varus nor valgus devia

tion a Anteroposterior view b Lateral view

Fig. 8. Poor Syme stump The heel pad has slipped to
tibual side of stump

periostially the blood supply to the heel flap is never endangered and the chances of skin neurosis are obviated. If the foot is removed from the outside inward and the skin fat flap of the heel is taken off the os calcis extra

Fig. 19. Prosthesis on Syme stump (right leg). No corset above knee. The patient has below knee amputation of left leg which requires corset on thigh.

periostially the blood supply of the flap will be cut off in a considerable number of instances.

There is a tendency for the heel flap to slide to the inside of the stump or to assume a varus position so that the pad of the heel is to the end of the tebia, like a side car on a motor cycle, and this, of course produces a useless stump. This sliding of the heel flap is very easily avoided by maintaining it in place over the end of the tibla with adhesive straps which are changed at intervals for a period of 4 weeks. At the end of this time the pad is well stuck to the tibra and there is no further danger of medial displacement.

For a male the Syme amoutation is the best possible amputation stump in the lower limb It has the advantage that the prosthesis does not extend above the knee. In the prosthesis the nationt can walk and stand longer than with any other type of leg amputation and it is possible for a patient to walk with a gait that is so close to the normal that the public will not know he is an amputee. In addition to these facts even without the prosthesis the nationt need not use crutches or hop Because of the length of the stump and because it is end bearing he can walk about the house at night on the end of the stump or when swimming or golfing he can get around to the shower and bath without having to carry crutches with him (Figs 12 to 19)

The Syme amputation is not a good amputation for a woman The prosthesis for this

amputation is bulky and unsightly at the ankle. From a cosmetic viewpoint, it is probable that women would not be happy with this type of amputation despite its superiority of function.

The British objection that this amputation will not stand wear and tear is without foundation. In Toronto there are many patents with a Syme stump who have been at work on the stump every day during the 25 years which have elapsed between wars. We have also used this type of amputation in some 60 patients and they are doing well. It has been used whenever possible in all Army Amputation Centers during the present war and the American surgeon will become more acquainted with its value.

#### AMPUTATIONS THROUGH FOOT

Many types of amputation preserving the Chopart amputation. These types of amputations are frequently tried because of the fact that they preserve the ankle joint. The Chopart amputation is doomed to failure and should not be done if the muscles in the front of the leg have lost their attackment to the stump of the fool. This is simple to determine. If these muscles have an attackment to the foot the patient can dorsifier the foot stump the attachment of these muscles to the tarius can be preserved the Chopart or any amputation through the foot should be done in preference to a higher amputation as the

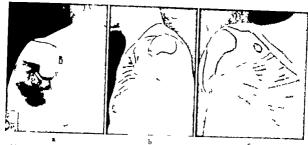

Fig. 22. Arm amputation stumps of no functional surgical neck of humerus. c, At pectoral insection

lat m of shoulder b Through (Courtes J B.

individual will be less handicapped. This of course does not apply to amputations done for arternal disease

In instances where the anterior muscle attachments to the foot the anterior tibial cannot be preserved the foot stump will gradually and inevitably assume a fixed equinus position due to the unopposed action of the gastrocnemius soleus muscle group and the foot stump in this position will be a handi cap rather than a benefit In instances where this muscle imbalance cannot be prevented a Syme amputation is preferable to the deformed remains of the foot (Fig 20)

## SHORT BELOW KNEE STUMP

A question which often faces the surgeon is how short a below the knee stump is useful and should be preserved. Or to put it another How much of the leg must remain before an amputation is done through the femur and the knee discarded? A good rule to follow is that any length of stump which can be seen to project when the knee is flexed should be saved. A stump which projects as little as 1 inch with the knee flexed is of value to the patient as a motor for moving the prothesis through the normal knee Although a patient with such an abbreviated below the knee stump will have to wear the same type of prosthesis as an above the knee amputee he will use the prosthesis better and will have greater security and control in going down

inclines A patient with a stump which projects 21 inche below the thigh when the knee is flexel will be able to do well with the ordinary below the kneeprosthesis and will net need in ischial bearing prosthesis. An occarmal leg maker will depreciate these short bel with knee tump because they are dimenli to nt but the knee should never be sacrificed in an individual who has good irculation if the stump can be seen to proie t when the tibia is flexed to a right angle on the femur (but 21)

#### UPPER INTREMITY AMEUTATIONS

Amputations of the upper extremity are not common in civilian practice and it is therefore rare that a civilian surgeon has much experience in dealing with the problems of these individuals. The general attitude of surgeons toward amputations of the arm is

That graph 4 stenu e harress emu er l t kery prosther! I plac on amount bon from pect sertion t shoulder (Courtesy of J. Box 5 g)

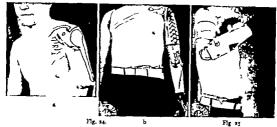

Fig. 34. a, Idea upper arm stump. b, Prosthesis on upper arm stump. Dotted area is space required for elbow block and mechanism. (Courtery J. Boss Serg.)

Fig. 35. Prosthesis for an above elbow stump. Dark triangular area contains lock which patient must manipulate with other hand to obtain different degrees of firston and extension. (Courtery J. Boss. Serg.)

to save all possible. This is a good attitude but it can be elaborated a little further as some arm stumps are more satisfactory than others

No amoutation through the humerus above the level of the humeral insertion of the pectoralis major produces a stump which has any functional value worths of consideration This fact does not mean that the head of the humerus should be removed unnecessarily as it tends to round out the shoulder and from a cosmetic viewpoint is desirable. Even though an inch or two of the humerus remains, if the pectoral attachment has been lost the end of the short piece of bone is pulled by the rotators into abduction and forward flexion. Amputations just below the pectoral attach ment also produce stumps of little value in motivating a prosthesis. At this level the remainder of the humerus stays opposed to the thoracic wall and just a little forward and backward motion of the atump is possible this movement is practically valueless in using an artificial arm. To maintain a prosthesis in place on these high amputations, an elaborate uncomfortable harness is necessary Because of the uncomfortable harness, the weight of the prosthesis, and the uselessness of the artificial extremity most patients ultimately discard the mechanical extremity and go about with an empty coat sleeve (Figs. 22 and 23)

The best site for an amoutation through the humerus to secure the bone length adapted to the most efficient use of a prosthesis is the level just above the beginning of the flare of the condyles of the humerus. At this site 2 to 3 inches of bone above the elbow are removed Amputation here is superior to a disarticulation through the elbow as it allows room for the mechanism of the elbow block, without placing the elbow at a lower level than the remaining arm and thus making a disproportionate forearm. The absence of the condules and the loss of the dustal 2 to 3 inches of the humerus do not detract enough from the functional value of the humeral lever to offset the cosmetic and mechanical difficul ties in the prosthesis (Fig 24)

The importance of saving the elbow joint when possible cannot be too greatly stressed. The functional value of the elbow to the upper extremity us even greater than that of the knee to the lower extremity Without an elbow joint under voluntary control, the arm amputee is limited to a few positions of the forearm, under the control of a mechanical lock which he must unlock with the other hand to release. In close quarters, even with the ideal humeral stump he may have to place the forearm of the prosthesis in one of a few positions available with the other hand Even a relatively short stump of the forearm

will obviate this difficulty to a large degree The short stump of the forearm need contain only a piece of the ulna and the necessity for removing the proximal end of the radius does not interfere with active flexion of the elbow since the brachialis muscle attaches to the ulna. An elbow joint is of great value even though it does not have total motion elbow joint is also of value. The condition of the humerus above the joint does not have to be normal to make the elbow worth saving As the arm is not a weight bearing extremity a fibrous union of the humerus may suffice for excellent use of the forearm stump since the corset of the prosthesis will stabilize the humerus, as the sidebars will stabilize a tlail joint at the elbow No unnecessary recon struction which through long immobilization might lend to stiffness of the elbow should be proposed when it will jeopardize function (Figs 25 and 26)

The ideal forearm stump is one through the junction of the middle and lower thirds of the forearm This level provides enough bone length for a firm grap on the cuff of the prothesis by the stump and permits 2 to 3 inches of the volar surface of the forearm below the elbow to be unencumbered by the prosthesis cust This eliminates interference with slevion of the elbow caused by the cuff pinching and impinging on the front of the arm This level is also just above the site at which the forearm becomes largely tendinous and avascular Such a stump has an excellent blood supply is warm and will tolerate well the rubbing of a prosthesis cuff Forearm stumps shorter than this are very useful but, as the distance be tween the end of the stump and the insertion of the biceps decreases the necessity for covering a greater proportion of the volur surface is increased and flexion of the elbow may be interfered with by the encasement of the prosthesis In the lower third of the forearm after the muscles have merged with their tendons there is poor circulation as only main arteries traverse this area through this area are cold and often evanotic Ulceration of skin is not uncommon in stumps in the lower third The difference in tempera ture at these two levels can be easily detected by palpation with the hand

lg kit Shirt one bone (ulna) below ell on stump िति । अं । अधिकारिक ls birt below ellow tu ।

Disarti ulation through the wrist joint is it is a fact aniputation. It has all the disards into a fact tump in the lower third of the fact arm. In a left in the inferior redioullust a term to be very painted on pronation and a ration. The fact access a loss of tablity a the jean which produces pain the jame of the disarties of the period of the peri

The turn which intain the proximal or protomil in little w t carpal bones is however a very useful and satisfactory stump from the fun to nal viewpoint. From the eismetic a peet it has a few disad The reason to the superiority of this stump to the disarticulation through the wrist are obviou Lirst of all it must of necessity be covered by tissue with a good blood upply -as the primar flap of the heel and upper half of the hand second the in ferior radioulnar joint is stable and painless because of the presence of its normal abut ments and ligamentous support. Third there are no bony unpudded prominences. The length of the stump containing carpal bones together with the slight voluntary flexibility of this distal end make it of considerable aid to the patient without a prosthesis stump can be used satisfactorily for a stabilizer in such activities as driving a car tving shoe laces tying a nicktie buttoning a coat et cetera. This stump also requires much less harness to keep the prosthesis in place and to motivate it powerfully (Fig.

Fig. 34. a, Idea upper arm stump b, Prosthesis on upper arm stump. Dotted area is space required for elbow block and mechanism. (Courtery J. Bras Surg.)
Fig. 5. Prosthesis for an above elbow stump. Dark triangular area contains lock which patient must manipulate with other hand to obtain different degrees of fersion and extension. (Courtery J. Bone Sure

to save all possible This is a good attitude but it can be elaborated a little further as some arm stumps are more satisfactory than others.

No amputation through the humerus above the level of the humeral insertion of the pectoralis major produces a stump which has any functional value worthy of consideration. This fact does not mean that the head of the humerus should be removed unnecessarily as it tends to round out the shoulder and from a cosmetic viewpoint is desirable. Even though an inch or two of the humerus remains, if the pectoral attachment has been lost the end of the short piece of bone is pulled by the rotators into abduction and forward flexion. Amputations just below the pectoral attach ment also produce stumps of little value in motivating a prosthesis. At this level the remainder of the humerus stays opposed to the thoracic wall and just a little forward and backward motion of the stump is possible this movement is practically valueless in using an artificial arm. To maintain a prosthesis in place on these high amputations an elaborate uncomfortable harness is necessary Because of the uncomfortable harness the weight of the prosthesis and the uselessness of the artificial extremity most patients ultimately discard the mechanical extremity and go about with an empty coat sleeve (Figs. 22 and 23)

The best site for an amputation through the humerus to secure the bone length adapted to the most efficient use of a prosthesis is the level just above the beginning of the flare of the condyles of the humerus. At this rate 2 to 3 inches of bone above the elbow are removed Amputation here is superior to a disarticulation through the elbow as it allows room for the mechanism of the elbow block without placing the elbow at a lower level than the remaining arm and thus making a disproportionate forearm. The absence of the condules and the loss of the distal 2 to 3 inches of the humerus do not detract enough from the functional value of the humeral lever to offset the cosmetic and mechanical difficulties in the prosthesis (Fig. 24)

The importance of saving the elbow joint when possible cannot be too greatly stressed The functional value of the elbow to the upper extremity is even greater than that of the knee to the lower extremity Without an elbow joint under voluntary control, the arm amputee is limited to a few positions of the forearm under the control of a mechanical lock, which he must unlock with the other hand to release. In close quarters, even with the ideal humeral stump he may have to place the forearm of the prosthesis in one of a few positions available with the other hand. Even a relatively short stump of the forearm

simple surgical procedure that is not mutilating and it would seem that in certain well selected patients its trial might be justifiable. The skin tunnels can be easily removed with out detracting in any way from the previous value of the stump if they are found unsatus factory.

## PHYSICAL THERAPY IN POSTOPERATIVE CARE

Physical therapy has a definite rôle in the postoperative treatment of the patient who has lost part of an extremity, and this rôle is too often not clearly enough understood by the surgeon Massage has very little place in returning the stump to its optimum condition Its only use is to free an adherent scar. Its efficacy in shrinking a stump is of little value and is far surpassed by the use of elitic bandages, properly applied and by the use f a temporary walking prosthesis such a pylon. The real shrinkage of the stump take place with activity and weight bearing and may be so rapid as to make a new leg a pen fit in a few weeks. Shrinkage should be a counted for to a large degree before the par manent prosthesis is obtained

The real value of physical medicine in the care of the amputee is in (1) the prevention and relief of contractures and (2) the de velopment of the muscles which will later be used in motivating the prosthesis

It is a very common thing for an amputee to develop a contracture of a joint in the involved extremity during the preoperative and immediate postoperative period. The joints most commonly involved in the lower extremity are the hip and the knee and in the apper extremity the shoulder

The flexion contracture of the hip is the most serious detriment to the proper use of a

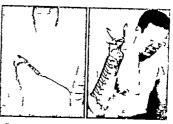

Fig. 3. Proathesis for forearm stump with carpal bones. I ft. Light harness. b, Powerful control split book in posit in (Ciu (esy J. Bone Surg.)

Frosthe is and is most frequently overlooked. The intraction is due to a shortening of the later dier abductor muscles of the thigh. With the tump abducted it is not obvious with the tump at lusted it may be very prominent. The left must makes it necessary for the quite it must make it necessary for the quite it must be defent to bend forward and thus it unit to gravity or to arch his back to any interest to gravity or to arch his back to any interest to fick and over his feet. The composition by increasing the lordosis leads to lack a he and to early arthritic changes in the line.

The titing of a prosthesis to an abducted or flexed stump is difficult and the deformity must be compensated for It is this deformity in the thigh stump which leads to the bucket striking the adductors and pubis and causing great discomfort. In very short thigh stumps the flexion-abduction contracture cannot be obviated and the bucket must be especially constructed to accommodate for it.

In all thigh stumps which preserve half the length of the leg this contracture can be re-

Fig. 32. Cosmetic latex hand on long carpal bone stump. a, left, Caucasan, cosmetic prosthesis on right hand. b Negro, cosmetic prosthesis on left hand. (Courtesy J Bone Su g.)

heved by stretching exercises and the development of muscles which prevent it. The development of these contractures can also be obviated by the simple expedient of having the patient he periodically on the stomach instead of sitting in bed with the hip flexed or propped up on pillows for 24 hours a day

Flexion contractures of the knee occur frequently in below the knee amputations and when present to over 10 degrees are a serious impediment to walking as the partially flexed knee lets the patient down. They are best prevented and this is easily done by having the patient contract the patiella, straightening the knee which also helps to prevent atrophy of the quadriceps muscle. When present they usually yield readily to passive stretching of the hamstring muscles and the capsular structures.

In the upper extremity the frozen shoulder with the humerus bound to the side, is easily prevented by keeping the amputated extremity on an aeroplane splint in 90 degrees of abduction. This is also a very great adjuvant to healing as it obviates the dependent edema and bogginess in the ussues. A contracture of the shoulder will yield just as any adhesive burstlus to peasure stretching of the contracted pectoral muscle and active exercise of the deltoid and rotators. No amputated extremity can be expected to use a prosthesis efficiently until all contractures are released

The efficient use of an artificial leg in an above the knee amputee depends on the full development of the gluteus maximus muscle which extends the hip and the adductor muscles which pull the leg toward the midline Too often after the invalidism which has accompanied the surgery these muscles are atrophied and weak Special exercises against resistance to strengthen these muscle groups should be instituted as soon as the stump is healed from surgery It does not take a masseuse to carry these out and the surgeon who removes the leg should instruct the pa tient in them and see that he carries them out to the point of good muscular development otherwise he has completed his job no more than has the surgeon who removes an eye and leaves an unsuitable socket for the artificial

The patient with a below the knee stump, in addition to having good musculature to extend and adduct the hip must have good muscles to extend the knee. Exercises to develop the quadriceps femons should be started early and continued until there is good strength in this muscle group.

The arm amputee must have a good deltold and if he has an elbow joint must have a good biceps to flex the proathesis.

#### BUMBLARY

The open circular or guillotne amputation is the safest type of procedure in the presence of infection. Proper after-care consisting of skin traction is a requisite to a good result in this type operation. A late secondary operation is necessary as a final procedure. This combination results in a better tailored stump than the open flap type of operation.

stump than the open flap type of operation.

2 Fasca and skin or skin alone should be the only covering of an amputation stump to muscle should be turned over the end of the stump. Aperiosteal technique is neither necessary nor sound. The nerve end should be well recessed under muscle. No chemical treatment of the nerve end is necessary. Complete hemostasis is necessary to good result.

3 Phantom limb is commonplace after amputation Painful phantom limb syndrome is another thing Drugs, alcohol, and psychic factors play a great part in the production of the latter Surgical removal of neuromas does not benefit the established 'painful phantom limb syndrome and any surgical attack on the syndrome will in almost

all instances result not only in failure to cure but aggravation of symptoms.

4 Pedicle grafts are not satisfactory for weight bearing stumps and will not stand the wear of a prosthesia. Skin grafting of open amputations is not necessary if proper after care consisting of traction, is carred out. Skin grafting does not facilitate final surgery

s End bearing stumps are desirable in undviduals under 40 years. They will stand up over time. The tendoplastic thigh stump is the best end bearing thigh stump. The Syme amputation is the best possible stump in the lower extremity if the foot must be sternfeed.

6 A below the knee stump which projects as little as r inch when the knee is flexed should be saved. It is of great help in motivating a prosthesis.

7 Any partial foot stump which has the anterior muscle groups attached should be saved. If the anterior muscle group is not attached a partial foot stump will inevitably go into severe equinus deformity and a Syme

amputation is superior

8 A humeral stump at or above insertion of the pectoralis major has no functional value Every effort should be made to save the clow joint even though the stump below

it is very short. Long stumps with the carpal bones in are excellent. Disarticulation through the wrist leaves a poor stump. The best are for forearm amputation is the junction of middle and lower third.

9 Indications for cineplasty are extremely restricted. It should not be considered except

in bilateral upper extremity amputees.

10 Physical therapy has a definite place in the preoperative and postoperative care of amputees. Massage is of very little value. The function of physical therapy is to prevent and release joint contractures, and to develop musculature.

## CANCER OF THE CERVIX

## A New Technique for Interstitial Implantation of Radium into the Parametrium

## E. EUGENE COVINGTON M.D., Baltimore, Maryland

NEW technique has been developed for interstitual implantation of ra dium into the parametrium and lymph nodes of the pelvis in cancer of the cervix. This is a preliminary report on the first 100 cases. It is not an analysis of a year results as some of the patients have been treated less than 5 years. The patients treated so far have all been chinical stages I (2 cases). II (17 cases) and III (80 cases) Interstitial therapy is not justified in stage IV cancer of the cervix.

#### REASONS FOR A NEW TYPE OF RADIOTHERAPY

The new technique was developed for sever al reasons chief of which are as follows

Inverse square law The inability to deliver enough irradiation into the parametrium and lymph nodes of the pelvis by the usual course of roentgen therapy combined with contracervical and intrauterine applications of radium. It should be emphasized that the loss of uradiation due to the inverse square law makes it impossible to concentrate a lethal (10 to 12 erythemas) dose of irradiation into the parametrum and lymph nodes along the lateral wall of the pelvis by the usual contra cervical and intrauterine applications of For example, if the true pelvis radium measures 12 centimeters in its transverse diameter the center of the pelvis (Intrauterme canal) is 6 centimeters from the lateral wall. Due to the inverse square law it would take 36 times as much radium (3600 mgm. hrs. of radium) in the cervix to get 100 milligram hours of radium into the lymph nodes along the lateral wall of the pelvis. This amount would be 1 crythema or about one-tenth the amount of irradiation necessary to destroy

From the Departments of Radiology of Mercy St. Joseph s, and St. Aguar Hospitale.

cancer cells present in the lymph nodes along the lateral wall of the pelvis. It is thus obvious that some form of interstitial therapy is necessary to concentrate a lethal dose of radium into the parametrium and lymph nodes along

the lateral wall of the pelvis.

Local recurrences in the cervix. There have been too many recurrences locally in the cervix and adjacent parametria following the usual amount of irraduation. In numerous clinics an average course of irradiation therapy is about as follows 2000 r to each of four pelvic fields followed by one application of contracervical and intrauterine radium (1000 to 4500 mgm hrs of radium) The author has seen too many positive biopsies after this form of therapy A two dose technique of radium application, the last being interstitial, is now advocated thus a greater amount of irradiation can be delivered to the cervix and a much greater amount to the parametria and lymph nodes of the pelvis. Pathologists have observed from autopey studies a high percentage of deaths from cancer of the cervix with the tumor still localized to the pelvis and no evidence of generalized metastases. About one-third (reports of clinics vary from 20 to 35 per cent) of all deaths from cancer of the cervix are due to urinary obstruction from extension of the tumor into the parametris. Morton noted that almost 50 per cent of the cases of cancer of the cervix had microscopic cancer cells present in the cervix at the time of operation. This high percentage of residual cancer after radium treatment is not general throughout the country but it does strengthen the argument that there are still too many cases in which the cancer still localized to the cervix, has not been eradicated by radium Tausalg and Meigs have found positive glands in the pelvic lymph nodes at operation in

almost one-third of all early cases (stages I and II) when they were not suspected clinic ally before operation Many observers Teahan, Pomerov, Pitts and Waterman and Arneson dissatisfied with their results in cancer of the cervix with parametrial extension are advocates of interstitual implantation of radium element needles or radon seeds into the parametrium through the vaginal route It is thus obvious that interstitual therapy is necessary and must accomplish two purposes a higher total dose of irradiation to the cervix. and a more equal distribution throughout the parametria and lymph nodes of the pelvis of a lethal dose of irradiation.

3 Trend back to surgery Within recent years there has been a renewed interest in the Wertheim type of panhysterectomy usually associated with the Taussig type of lymph node dissection for selected cases of early (stages I and II) cancer of the cervix. Many gynecologists now believe the combination of irradiation followed by panhysterectomy will give a higher percentage of 5 year cures than either procedure alone. It is certainly true that a panhysterectomy is a much safer surgical procedure after the gross tumor has been almost entirely destroyed and the secondary infection cleared up by previous irradiation therapy.

Surgeons have three good reasons for their belief in a radical type of panhysterectomy for cancer of the cervix (1) There are still a few cases in which the cancer of the cervix cannot be controlled by the present-day type of irradi ation. (2) About one third (Taussig 333/5 per cent, and Meigs, 17 per cent) of all early cases (stages I and II) will have cancer cells in the pelvic lymph nodes at operation. Irradiation has a delaying effect on such cancers, but a low 5 year cure rate. (3) Improvements in surgical technique especially the modern ad vances in the control of infections, have so lowered the operative mortality and morbidity that panhysterectomy is a safer procedure than in former years. Panhysterectomy then should offer a better 5 year cure rate in early cases, and it is now up to the radiologists to offer something equal to this definite step for ward obviating the necessity of resorting to major surgery

TECHNIQUE OF RADIOTHERAPY

The author advocates a new technique for delivering a greater dose of irradiation to the cervix and a much greater dose equally distributed throughout the parametria and lymph nodes along the lateral wall of the pelvis

First radium treatment. As the first treat ment 3600 milligram hours of radium with I millimeter platinum as a filter was used as follows One long rubber tandem (oo mgm of radium X 24 hrs. = 2160 mgm, hrs of radium) was inserted into the intrauterine canal and a rubber tandem (30 mgm of radium × 24 hrs. = 720 mgm hrs. of radium) was packed with gauze as far laterally as possible into either lateral vaginal fornix. This procedure gave a fairly equal distribution of irradiation through out the pelvis Aserious mistake and probably the most common cause of radiation necrous is to concentrate a large quantity of radium in a small area usually the contracervical region giving an overdosage and thus necrosis in that small area and not enough throughout the pelvis. Packing the rubber tandems in the vaginal fornices with gauze is better than colpostat technique There are so many anatomical variations and variations in the amount of cancer present that in many instances the colpostat technique was impractical. Five grams of sulfanilamide was routinely dusted on the cervix before the gauze packing In the present day of sulfon amides and penicillin to control infections there is no reason to use roentgen therapy first for this purpose

Reenigen therapy Within a few days (usually 1 to 7) after the first radium treat ment roentgen therapy was started which was as follows 2000 to 2400 r was given to each of four pelvic fields over a period of 4 weeks. The physical factors were 400 kilovolts, Thoreus filter (1 75 mm sn 8 mm. cu and 1 mm. al.) so centimeters distance, and 15 centimeter cone portals. This technique gave a 42 per cent depth dose (42 per cent of 8000 r = 3360 r in the tumor) into the cervix (10 cm depth) and adjacent parametria.

New interstitual radium technique As soon as the roentgen therapy was completed (usually 30 to 35 days after the first radium

treatment) the second treatment or inter stitial implantation of radium was done. By this time the secondary infection was usually cleared up and most of the gross tumor especially the friable type of cauliflower growth, was almost entirely gone. A search of the literature reveals that no one has used exactly the same interstitial technique of radium as will now be described in detail as the author's technique Four small incisions (5 cm.) were made in the vaginal mucosa at equidustant points as far laterally from the cervix (usually 2 to 3 cm.) as possible. The incisions were actually in the 2 4 8, and 10 o clock positions around the cervix (Figs 1 2 and 3) It should be emphasized that the cutting was only through the vaginal mucosa and not into the parametria. A long Kelly clamp was next used to dissect a long tract (usually 2 to 4 cm) into the parametrium through each of the four incisions. This dissection is the most dangerous part of the whole procedure but by care patience and experience the author has now done this new procedure in well over 100 patients with no evidence of injury at operation to a blood vessel ureter bladder or rectum in a single case.1 After dissection of the four tracts as described four rubber tandems were made up as follows two tandems contained 25 milligrams of radium, and two tandems contained 20 milligrams of radium (usually 2 tubes of 10 mem each) A rubber tandem was then inserted into each of the four tracts. This gave 1260 milligram hours of radium (45 mgm of radium × 28 hrs. = 1260 mgm. hrs. of radium) into either parametrium or a total of 2520 milligram hours of interstitlal radium. A long rubber tandem (60 mgm. of radium X 28 hrs. = 1680 mm hrs. of radium) was then in serted into the intrauterine canal. Five grams of sulfanilamide was routinely used locally and the vagina was packed with gauze. The gauze packing helps to push the bladder and

#### TOTAL RADIATION GIVEN

A glance now at Table I will show that irradiation given over a period of 35 to 40 days, by use of a two dose radium technique, the last being an interstitual application, combined with roentgen therapy as described accomplished two purposes a high total dose given to the cervix (1840 mgm hrs. of radium + 3360 r-42 per cent of 8000 r-of roentgen therapy) and a high total dose fairly evenly distributed throughout the parametria and lymph nodes of the pelvis (1080 mgm hrs. of radium + 3360 r of roentgen therapy to either parametrium) The total irraduation given directly into the tumor is thus 7800 milligram hours of radium + 1360 r of roent gen therapy

#### CONTRAINDICATIONS YOR INTERSTITIAL RADIUM THERAPY

Interstitial implantation of radium was always discontinued for any of the following three conditions

I Radiation fibraris There was an occasional patient, most commonly an ekierly woman who would develop so much fibraris from the first radium treatment and the 8000 r of roentgen therapy previously given that the

This was dissection and implicate aims or others techniques was done served limes to the arrayer years on first activates below extracted for on parlamit. The classerings of the intent was done by the answer described and disseasy radious trainess were implicated. The photomic was expect and the least flow of the 4 trainess were written to the answers of the fact these arrays are the contract when when the answers of the section of the section, when the correct and learn's with of the parks were measured. That tandems were smally in 5 continues on these lates to correct, markle as the lapt blood veneral, and learn's with

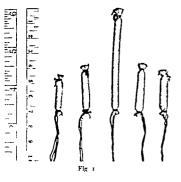

Fig. 1 Photograph of the actual radium tandems used for this series of 100 cases. There are a rubber ta dems (2 contain a 25 mgm, tube of radium and 2 contain a 20 mgm. or a 10 mgm tubes of radium) for interstitual implantation into the 4 carefully dissected tracts of the parametria and a long rubber tandem (either 3 20 mgm tubes of 2 30 mgm tubes of radium) for intrauteri e application. The tandems are made of Dakin's tubes (2 mm of rubber) with strong silk strings attached. The filter is thus I millimeter platinum, 2 millimeter rubber It will cause less necrosis than radon seeds (3 mm gold filter)

Artist's drawing of implantation. Note the positions of the 4 tandems for i terstitial implantation situated at equidistant points (s to 3 cm. lateral to the cervix) at 2 4, 8, and 10 o clock positions. Note the absence of a contracervical application. The author beheves they concentrate too large a dose of irradiation to the cervix and thus cause necrosis.

Fig 3. Photograph of a roentgenogram showing the locations of tandems and the long i trauterine tandem (the s large radium capsules centrally located). Note that the a tandems in either parametrium are about one-half the d stance from the middle of the pelvis (intrauterine canal) to its lateral wall thus givi g a wide and equal distribution of a lethal dose (1260 mgm hrs. of radium) to either parametrium.

dissection was difficult and probably too dangerous. Interstitual therapy would surely cause more fibrosis and thus increase the possibility of late complications, i.e. urinary obstruction from stricture of the ureters, sciatic nerve pain from the pressure of scar tissue on the sciatic nerve plexus or stricture of the rectum

Infection An occasional patient, usu ally with the infiltrative type of lesion still had too much infection present following the

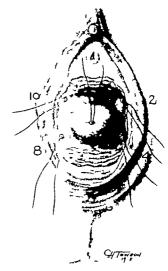

Fig a

Fig 3

previous radiotherapy to justify the risk of dissection and parametrial implantation of radium. A persistence of infection was nearly always due to two causes (1) radiation necrosis from a previous overdosage of radium concentrated to a small area or (2) uncon trolled cancer. A combination of local infection and radiation necrosis was usually a sign of a bad prognosis.

3 Advanced cancer Many times examina tion under anesthesia would reveal a more advanced lesion than was thought present before operation. This has been a common error Many of the cases, especially in the early days of development of the new technique called stage III we would now classify as stage IV. The personal equation and en thusiasm of different authors vary and thus the differences noted in the classifications of the clinical stages of cervical cancer.

#### ADVANTAGES OF INTERSTITIAL RADIUM THERAPY

The author claims the new technique of interstitual radium implantation into the para metria has the following advantages (1) It eliminates the necessity for an abdominal operation (2) Positive biopsics after treat ment are less than was noticed by the older method of therapy thus the 5 year cure rate should be higher (3) It gives a more equal distribution and higher total dosage of irradia tion in the parametria and lymph nodes of the pelvis. There have been only 4 cases (4 per cent) of death from urinary obstruction due to parametrial extension as contrasted with the 20 to 35 per cent as recorded in the literature (4) The filter (1 mm pt + 2 mm of rubber) causes less necrosis than radium needles or radon seeds. Radon seeds have a filter of 3 millimeter of gold which allows enough beta rays to pass through to cause necrosis adjacent to the seeds. (5) There is no danger of punc turing a blood vessel ureter or bladder when the blunt rubber tandems are inserted into the four carefully dissected tracts. This is a sen ous danger when radium element needles or radon seeds are inserted blindly into the para metrium (6) Radium element needles with silk strings attached will occasionally get hung in the tissues on attempted removal. Several

observers have had this embarrassing experience making operative removal necessary. This mishap has not occurred with the rubber tandems placed in the carefully dissected trans-

#### COMPLICATIONS OF INTERSTITIAL RADIUM THERAPY

The possible complications of this new technique for interstitial implantation of radium into the parametria were both early and late.

Early complications The dangers or possible early complications from the operation were as follows (1) damage to the ureters with ex travasation of urine (2) damage to a large blood vessel with hemorrhage (2) opening the pentoneal cavity with peritonitis as a result and (4) pelvic cellulitis through any one of the four openings into the parametria. In this first 100 patients treated by the new technique none of these possible mishaps have occurred. This fact alone convinces the author that the new technique is certainly a safe procedure and could be learned easily by any radiothers pist with surgical training Cystitis, proctitis, irradiation sickness and erythema with desquamation of the skin around the pelvis were noted with about the same frequency with the new technique as was noted by older methods They were at times troublesome and annoying to the patient but never serious.

Late complications The late complications from interstitial radium implantation were more serious than the early and were noted as follows (1) A fairly severe proctitis was the most common late complication and was noted in 6 patients, 1 of whom developed a stricture severe enough to require colostomy The other 5 patients still have occasional attacks of diarrhea with bloody mucus in the stools. Proctoscopic examination showed the typical picture of irradiation proctitis, usually most pronounced about 6 to 8 centimeters above the anus. All 6 of these patients are clinically free of cancer (2) Rectovaginal fistulas have been produced in 4 patients 3 of whom probably had stage IV cancer and should not have been treated by interstitial therapy All 3 of these patients have necroses, fistulas, and still have positive biopsies after the heavy total dose of irradiation given in this series. The fourth patient is living and clinically free of

cancer over 5 years, but she still has the fistula The author considers this fistula was due to overrradiation (3) Irradiation necrosis of the cervix was present in several cases, especially the late stage III (or IV2) cases in most of which cancer was still present locally in the cervix after treatment. One patient has devel oped late irradiation necrosis of the cervix several months after treatment and is still clinically free of cancer (4) Urinary obstruc tion was the ultimate outcome in 4 patients each of whom had cancer clinically in the para metrum and in a cancer was proved by autopsy. This complication was studied care fully because interstitial radium therapy always produces more fibrosis than external irradia tion. It is certainly safe to say that extension of cancer into the parametrium was several times more common as the cause of obstrution to the ureters than irradiation fibrosis (5) Secondary vaginal hemorrhages were a serious complication in 7 cases. There was also I fatality from rectal hemorrhage every case of secondary hemorrhage the pri tient had uncontrolled cancer in the cervix

Briefly to summarize the complications of interstitial irradiation there were no early complications from the implantation there were 6 cases of irradiation proctitis 1 case of rectovaginal fistula and 1 case of radi ation necrosis of the cervix as late complica tions. All the remaining cases of fistulas necroses secondary hemorrhages urmary ob structions and distant metastases were due to uncontrolled cancer and not to overgradiation

#### RESULTS

The primary purpose of this paper was to show the necessity of interstitual radium ther apy for cancer of the cervix and the advantages of a new technique used by the author in 100 cases. It is not a 5 year study as a few of the patients were cared for less than 5 years ago Seventy-six patients (76 per cent) are still living and under observation and 24 patients (24 per cent) have died of cancer The Lnown causes of death were as follows 3 patients had rectovaginal fistulas, 2 had bone metastases 2 had pulmonary metastases 4 died of urinary obstruction 7 had secondary vaginal hemor rhages, and 1 died of rectal hemorrhage

#### SUMMARY AND CONCLUSIONS

From a study of the 5 late complications of irradiation the causes of death in 24 patients and the high percentage of positive biopsies of lymph nodes of the pelvis found at operation by surgeons it should now be obvious that a higher total dose of irradiation should be given to the cervix and a much higher total dose equally distributed throughout the parametria and lymph nodes of the pelvis

There were no early complications from the interstitial implantation of radium but there were 6 cases of irradiation proctitis i case of rectovaginal fistula, and I case of radi ation necrosis of the cervix as late complications. The 22 death, were the result of uncontrolled cancer of the cervix and adjacent parametrium

The advantages and contraindications of the new type of interstitial therapy were discu sed in detail. Emphasis was placed on the great i satety of this procedure over other I simi I inter titial therapy

It author ha tried to accomplish the 1) To eliminate the necessity of a mai r u a il procedure for early carcinoma the creat (2) To improve the complete radication the growth in the cervix. There here been i her positive biopsies after treat nunt thu the 5 year cure rate should be bet ter There have been only 4 deaths (4 per cent) from stage II cancer of the cervix and none from stage I This rate is far better than was obtained by previous methods of radiotherapy (3) To reduce the number of deaths from parametrial extension of cancer by giv ing a higher total dose of irradiation equally distributed throughout the pelvis. This has also been effected as only 4 deaths (4 per cent) were due to urmary obstruction contrasted with the usual 20 to 35 per cent recorded in the literature

of salaw appeared in the bab's mouth and it was necessary on several occasions to suck these away in order to establish a satisfactory airway. On the second day of life a dilute formula was officred but the feedings were promptly regurgitated. All at tempts at feeding were followed by respiratory difficulty and cyanools. The infant was seen in consultation by Dr Adelman and was referred to

this bospital with a diagnosis of esophageal atresia. Physical examination on entry showed a well developed and well nourished white male infant in no acute distress Temperature was 99 2 degrees F respirations 24 pulse 120 The color was good and there was no cyanosis at the moment. The skin had a slightly interior tint which was regarded as a physiological jaundice. The head eyes ears, nose and throat were normal. The sides of the chest moved equally, there was no intercostal retraction percussion note was resonant over both lung fields. There were numerous fine, most rales and coarse rhonchi throughout the entire chest more marked at the right apex. The heart was not enlarged to per cussion. The cardiac sounds were of good quality and the rhythm was regular. There was no murmur The abdomen was slightly tympanitic, and was normal to palpation The liver edge was felt just below the costal border The genitalia, extremities and reflexes were normal. By rectal examination meconium was found on the examining finger

Roenigenologic examination was made immeditable from the following a first admission. Under the fluoroscope a No 8 French urethral catheter was passed through the maints nose and down into the esophagus. The catheter would not pass into the atomach since it met

some obstruction — the a iddle portion of the esoph agus — Two cubic entimeters of lipitodol were now introduced through the catheter. A blind esophageal pouch (atreasa) was demonstrated at the level of the 4th thoracic vertibra (Fig. 2). Fluoroscopy and film studies showed a considerable amount of gas scattered through the stomach and intestines indicating the existence of a fistual between the traches and the lower segment of esophagus. There were patches of a telectasis and emphysems throughout both lung fields the changes being most marked in the right upper 1 bbe.

The infant was placed in an oxygen tent. The upper blind end of the esophagus was kept cleared out by an inlying catheter which was passed in thr ugh the nose and was connected to a Wangen t n u ti n apparatus Intramuscular penicillin val tarted in loses i 3 000 units every 3 hours > hum ulta hazine was given subcutaneously with and ubsequent doses of t 4 h urs I arenteral fluids were Lini o ulic centineters of 5 per cent al mit in at rittray n u ly and 100 cubic centi-Llu nt gluc su in 0.47 per cent 1 m t t 1 by Linially Att r 12 hours of this الهin ril lad la i lisal peared from the rat cibtin se'med optimal for Ç ja at

the infant was placed in a prone position with the right boulder elevated slightly (Fig. 3). A curved incusion was made just inside the medial border of the right scapula running downward and outward around the angle of the scapula. The superficial muscles were divided and the scapula was reflected upward and laterally, and the costal cage exposed. The erector spinae muscles were mobilized slightly toward the miles. Subperiosteal resection of the segments (about 3 cm long) of the syd 4th and 5th ribs was now carried out. The bundles of intercostal muscles with their accompanying nerves and vessels.

were divided. The pleura was then stripped forward by blunt dissection from the vertebral bodies and the anygon with exposed. This was was doubly as the stripped forward in the stripped forward the transfer and divided. Dissection was continuous out the transfer and the stripped forward the stripped forward the stripped forward the stripped forward to a point opposite the lower segment of esphans had a hattilous communication with the posterior strates of the traches about 35 inch above the carina (Fig. 4a). There was some thin arcolar tasue between the two esphagael segments. The lower part of the

esophagus was now extensively mobilized as far down as the diaphragm though this was accomplished at considerable risk to its blood supply. The tracheo-esophageal fistula was ligated with No 2000 silk close to the traches and was then divided (Lig 4b) Along slit was cut in the lower esophageal tube The upper esophageal pouch was extensively freed from surrounding structures up to the base of the neck. The thinnest area of this pouch was on it anterior surface along which an opening was made Stay sutures of No 00000 silk were placed in the four quadrants of each esophageal end The No S urethral catheter in the nose and upper esophagu was now pushed downward by the anesthetist so that it could be threaded into the lower segment an i into the stomach. The near ends of the stay sutures were first tied following which the far ends were tled and thus the walls of the esophagus were rolled inward at the anastomosis Next 7 or 8 interrupte ! sutures were used to join and turn in the musculars between the stay sutures. An effort was mad t establish an oblique type of union in the belief that this might have less tendency to subsequent strictum formation. In anticipation of this type of junction slits had been made in each segment and it wa thought desirable to make each slit where the respective segment seemed thinnest. In each case the was on the anterior surface. Unfortunately this procedure necessitated rotating the lower segment through a twist of 180 degrees in order properly t appose its opened end to that of the upper pouch (However this twist has in no way interfered with the subsequent function of the esophagus) mediastinum was thoroughly irrigated with soline sucked out, and then filled with 25 000 units of peni cillin solution A narrow strip of soft rubber drain was placed near the anastomosis and was led out through the inferior angle of the skin wound The chest was repaired by joining the intercostal muscl bundles posteriorly closing the superficial muscl layers and then approximating the skin Deknat ! No occoo silk on atraumatic needles was employed throughout the procedure for both the cophageal ana tomosis and the wound closure. The infant stood the operation quite well

Postoperative course. The baby was again placed in an ovegen tent which was discontinued in 24 hours. Four hours after operation breast mill was injected through the inlying gastric tube and was increased in a few days to supply full calonic requirements. A transfusion was given after operation and on the following day. Clyses were continued for 4 days. The infants pulse and general condition were extremely statisfactory throughout the post operative period. The mechastinal drain was removed on the 5th day, there having been a discharge of only a few cubic centimeters of thin, sero-oan resulted with the continued of the sero-oan resulted with the continued of the sero-oan resulted with the course of the sero-oan resulted with the sero-o

quickly through the esophagus. There has been some visible constriction at the site of anastomosis and the lumen of the esophagus above this level has been somewhat larger than the lumen below it However dilatations of the esophagus were not done at any time during the first year of life The child s general physical condition has been excellent (Fig 6) and the weight gain has been most pleasing (Fig 7)

At about 1 year of age the child began to have some difficulty with swallowing of solid food and was returned to the hospital for short periods in the 13th

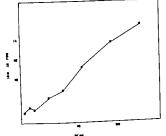

Fig 7 Patient's weight chart for first half year of lif indicating satisfactory gain.

excellent general status.

14th, and 15th months of life at which time the esophagus was dilated respectively to No 30 (French) No 30 and No 41 Following this last and more thorough stretching deglutition has been very satisfactory. When last seen at 20 months of age there was no hesitation in swallowing DISCUSSION

At least five methods of primary anastomosis have been successfully employed for repair of esophageal atresia Each of these procedures has certain factors which recommend it as a valuable approach to the establishment of esophageal continuity in infants. Final evaluation of each method is not possible until larger series are available for study but it is fitting at this time to point out some of the apparent merits or drawbacks of the different forms of anastomosis.

Haight (2,3) has recommended a primary repair whereby the tiny and thin distal seg ment is telescoped for a short distance into the upper segment in such a way that the entire thickness of the wall of the lower segment is joined by interrupted sutures to the mucosa and the submucosal layers of the upper segment (Fig 8a) The muscularis of the upper segment is then lapped over and at tached by sutures to the muscularis and adventitial structures of the lower segment

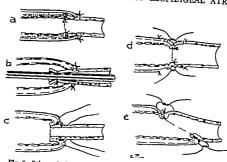

Fig. 8. Schematic drawings of types of esophageal anastomoses. a, Method of Haight. b, Daniel's procedure. c, Humphrey's rechnique. d Ladd's method, employing tension sutures to relieve strain on line of union. e. Operation here reported. Ends of multiple bite sutures are tied opposite ends of these sutures are then being tied to roll in ends of exophagus. Oblique anastomosis.

The outstanding advantage of this method would appear to be in the sleeve-like over lapping of the muscular layers which obviously should give a great deal of strength to the anastomotic repair The greatest draw back with this method would probably be the difficulty of placing the first row of interrupted sutures since the distal segment is usually small quite friable and easily torn. Hence there is considerable chance for the sutures to cut through or pull out, particularly if the segments have to be drawn together under any great tension Aside from any theoretical disadvantages of the method, Haight's ex perience to date shows that in 3 cases a brilliant result has been obtained the babies have not needed gastrostomies and each has been able to take feedings satisfactorily In 2 patients a fistula developed through the back, but each has healed spontaneously In another individual, a tracheo-esophageal fistula reopened Hence in each of these latter 3 cases it is obvious that some portion of the umon had broken down after operation Never theless Haight's reports have shown more recoveries from direct anastomoses than has any other publication to date.1

Since completion of this manuscript one of ms (R E G) has attempted went more operations for enophagual attents by the Haight technique, so of these Ada survived and at the moment we feel that this is the manuscript of the moment which is the statement in bubble 11 in

Daniel employed an ingenious method for the surgical union of the two segments in esophageal atresia After freeing and opening the upper and lower ends a catheter was placed in the nose led down through the upper segment, and threaded through the lower segment into the stomach. This catheter was used for upward traction after the esophageal end was tied to it. Thus the lower part of the esophagus could be pulled inside of the upper segment, to which it was then anchored with a number of interrupted stitches joining the muscle layers (Fig 8b) The chief disadvantage with this procedure would seem to be that the esophagus is com pletely obstructed until the encircling ligature breaks or until it cuts through the esophageal substance During this period of total obstruction saliva can accumulate and possibly spill over into the larynx and trachea. Some of this difficulty might be obviated by very careful nursing care during the postoperative period, so that any accumulated fluid could be frequently sucked out of the mouth and pharynx. It must be pointed out that Daniel was able to overcome a defect in which there was a very long separation between the two esophageal segments. Whether or not such a method will be productive of a higher percent age of strictures at the anastomosis site is as

It is needless to emphasize that great delicacy must be employed in the performance of esophageal anastomosis in babies. The tissues particularly of the lower segment, are extremely fragile and are easily injured Every effort should be made to handle them with utmost gentleness and to avoid squeez ing them with hemostats forceps, or other instruments The stay type of suture advised by Ladd provides an admirable handle for traction and for manipulating the esophagus When one of these stitches has been placed all subsequent sewing can be accomplished without grasping the esophagus with a metal he instrument. In the case here reported it seemed to us of considerable importance that the esophagus was not touched with forceps more than three or four times during the entire surgical procedure To complete such tiny operations successfully it is necessary to have a few instruments of diminutive size. A small blunt periosteal elevator or a septum elevator-dissector is essential for stripping the parietal pleura from the thoracic cage and the mediastinal structures Tissue forceps should be no more than 3 or 4 inches in length and should have delicate toothless points Scissors may be curved or straight, but should be no more than 3 or 4 inches in length. Of prime consideration is the type of suture material and the needle upon which it is threaded. We believe that fine braided silk is superior to any other type of suture material Size No 00000 has adequate strength and a very small caliber When attached to a No 9 Deknatel atraumatic needle, it makes a superb ma ternal for use in bables

The choice of anesthetic agent must of course depend upon the circumstances in a given clinic. Local novocain infiltration has been frequently employed avertin plus novocain has been frequently employed avertin plus novocain has been favorably commented upon in some instances ether has been preferred Various authors have condemned general anesthesia but we are convinced that it greatly facilitates the performance of the operation and need not be productive of shock or untoward reaction. In the case here reported and in other instances in this hos pital cyclopropane has been the anesthetic of choice. It gives sufficient relaxation and

carries a high concentration of oxygen When supplied through a tightly fitting face mask it can be given under positive pressure if by accident the parietal pleura should be pierced at any time the lung can be easily expanded. Our selection of cyclopropane has been dependent upon the availability of an expert anesthetist who has had wide experience with its use in babies. Where such conditions do not prevail local anesthesia would probably be safer.

Discussion has arisen concerning the ad vantages of leaving a small rubber tube in the reconstructed esophagus. In our case a No 8 French catheter was led through the nose, down through the esophagus and into the stomach-and kept there for 8 days. We considered it to have value as a semi rigid structure for keeping the segments of the esophagus in line Furthermore it was enor mously useful for feeding purposes during the immediate postoperative period ably an inlying catheter can produce pressure necrosis in the anastomotic area, but we are inclined to minimize this danger Previous experience indicates that some infants will tolerate a tiny rubber tube in the nose for protracted periods of time while others de velop such a violent reaction to it that nasal stuffiness and accumulation of secretions greatly embarrass the baby a breathing. In short if a catheter is tolerated well it is probably a valuable therapeutic agent however too much reaction is set up in the nose or throat it is folly to keep a tube in place

The use of a gastrostomy is likewise a moot point. In the present case gastrostomy was performed 8 days after the esophageal repair but it was kept open for only a week. This patient fared so well that possibly he could have survived without the gastric opening In 3 of Haight a patients no gastrostomy was employed. In general, it would seem to us that the establishment of a Stamm gastrostomy under local anesthesia can be such an innocuous procedure that it should be almost universally done a day or two after the esophageal repair the inlying esophageal cathe ter could be omitted and all oral feedings could be withheld for several weeks in order

to allow the best possible esophageal healing While this routine would obviously impose a gastrostomy on some patients who might have survived without it there would doubtless be improvement in overall results when em ployed in a series of cases

The necessity for esophageal dilatations and the frequency with which they must be re peated will depend upon the tightness of any existing stricture and the severity of the dysphagia The size and the function of the exophageal canal can be observed by a swallow of barium (or lipiodol) and fluoroscopic examination. However we are convinced that esophageal dilatations should not be performed solely on the basis of any roent genologic findings which suggest a constriction at the site of anastomosis. Indeed, the in dications for dilatation should depend almost entirely upon the subjective symptoms which occur during the ingestion of feedings. One gains the impression that scar tissue (if not too great) at the site of an anastomosis may give trouble for a temporary period, but that the symptoms can become much less as the child grows older and the esophageal lumen becomes greater In short the lesser degrees of stricture may be troublesome at first, but they do not necessarily imply that dilatations will be required indefinitely

Observations are reported upon a baby with congenital atresia of the esophagus and associated tracheo-esophageal fistula. Surgical correction was undertaken through a right, extrapleural mediastinotomy esophageal fistula was closed and the two esophageal segments then joined by a long The baby was discharged from the hospital 19 days after operation Esophageal dilata tions were not required during the ensuing year but were performed thereafter The child is in excellent health at 30 months of age. The surgical method is one which can be employed only when the esophageal segments he close to one another or when they can be adequately mobilized to allow satisfactory approximation. Under such circumstances,

# the technique merits further trial in future REFERENCES

# PANCREATIC HETEROTOPIA

Review of the Literature and Report of 41 Authenticated Surgical Cases, of Which 25 Were Clinically Significant

JORGE J DE CASTRO BARBOSA M D MALCOLM B DOCKERTY M.D., and JOHN M WAUGH M.D., F.A.C.S., Rochester Minnesota

HE presence of pancreatic tissue in an aberrant location, without connection with the main pancreas can at the present time no longer be considered merely as a rare and casual post mortem discovery or as an unusual and interesting but incidental finding at operation. In view of the multiple surgical cases of clinical significance reported in the medical literature it is a condition that should be kept in mind, recognized, and taken into due consideration by the surgeon who operates on the surrointestinal tract.

In the past 5 years there has been an in creased interest, both of the clinician and of the surgeon in conditions referable to the pancreas. Much study has been done in various sectors in this field. Much of this work has been dedicated to the clinical study and surgical treatment of hypoglycemia and hypermaulinism There have been examples reported in which aberrant pancreatic tissue was the site of hyperfunctioning insulinproducing, benign or malignant neoplastic there. The presence of a functioning aberrant alet cell adenoma or adenocarcinoma can possibly explain the enigma of some cases of idiopathic or so-called spontaneous hypoglycemia, in which an exploration does not reveal the presence of any tumor in the main pancreas.

Aberrant pancreatic nodules have at cer tam times caused embarrassment to the surgeon At other times far from being merely an incidental finding heterotopic pancreatic tissue has been known to be the

source of considerable trouble and to be the cause of serious conditions for which a major surgical procedure had to be instituted to obtain relief

The collection of cases in the literature especially in the more recent years, has been illustrative and revealing. The reports how ever have all been accounts of isolated in stances and no large group of cases has yet been presented from one single source the largest series being that of Branch and Gross, who presented 24 cases in only 5 cases however was heterotopic pancreatic tissue encountered at operation and in only 4 was it causative of symptoms.

In an endeavor to make a substantial contribution to the casuistics of this subject we have attempted to make a detalled clinical and pathologic study of all the surgical cases of pancreatic heterotopia found in the records of the Mayo Clinic. There is a relatively large group of cases with clinical significance especially in the more recent years.

#### MATERIAL AND METHODS

We reviewed a series of 82 surgical cases. Twenty five of these were authentic cases (confirmed by microscopic examination) of pancreatic heterotopia in which the heterotopic pancreatic tissue was clinically significant, in that either it was found to be the only or main lesion for which the patient was taken to the operating room or it was one of the lesions contributing to the production of symptoms. These cases are summarized in Table 1

Sixteen cases of the series were authentic cases of pancreatic heterotopia in which the heterotopic pancreatic tissue was merely found incidentally at operation during the course of a surgical procedure performed for some other lesion

Abrigment of thesis submitted by Dr. Barbosa to the Faculty of the Gradeaute School of the University of Minnesota in partial self-liment of the requirements for the degree of M.S. in Surgery Iron the Division of Surgery Mayo Foundation, and the Scribe an Sorgical Pathology and the Division of Surgery Mayor Foundation, and the Mayor Clinic.

of pancreatic beterotopia in which the beterntopic pancreatic tissue diagnosed grossly by the surgeon as such, was found incidentally during the course of an operation performed for some other surgical condition and was thought not to be of clinical algorificance

#### GENERAL CONSIDERATIONS

Definition Pancreatic heterotopia is defined as being the presence of pancreatic tissue outside its usual or habitual location and without anatomic relation either of continuity or of vascularization with the Dancreas proper

Literature A complete review was made first of the early literature and second of the recent literature (Tables II and III) As precisely as we can determine, from 1727 to March, 1044, approximately 430 cases have been recorded in the literature to which we add the cases of our series (Table III) which includes at authentic cases and at unconfirmed cases.

Embryology and hypotheses of origin Areg gave a very clear description of the organogenesis of the pancreas. The classical descriptions are generally in agreement as far as the number and general topography of the pancreatic anlagen are concerned. They differ however when it comes to describing the phases through which the anlagen go in order to form the definitive pancreas. In 1030 Delmas presented his findings after following the evolution of the pancress on reconstructions made by Born's method on human embryos from 5 to 27 milhmeters in length Delmas concluded that the total pancreas is completed at the 27 millimeter stage According to his research, which was the most recent and thorough work that we found on this subject, the dorsal pancreas forms the head of the pancress (primitive dorsal anlage) and the body and tail of the pancreas (bud from the dorsal anlage) The ventral pan creas forms the preduodenal process the pancreas minor of Winslow and reinforces the dorsal part of the head of the pancress. The ventral pancreas is the only anlage that tends to encircle the duodenum

Practically all the concepts of the etiology of heterotopic pancreatic tissue maintain that

Brusch and Organ is 1933 reported 14 cases of their own bridges an additional to bross the literature.

Brusch and Organ is 1933 reported 14 cases of their own bridges are short information of the literature of Total cases Infividual contribution

this anomaly is antenntal in origin. It is evident that one single concept does not ex plain all cases however much basis of truth it possesses Our attitude in regard to these hypotheses is eclectic. Of those concepts presented three deserve mention for being the ones that seem most logical to us and that are based on embryologic knowledge namely, Horgan s, Lordy s and Warthin's concepts. Horgan expressed the belief that before the coalescence between the two anlagen takes place during the partial circumrotation of the posterior and anterior pancreatic anlagen, when there is a migration of the body upward

the branching ducts, as a result of the organs being packed together come into contact with the walls of the mesentery, stomach, or in testune growing in the opposite direction On these they become engrafted because of noninflammatory adhesions of fetal life Later during the growth and movements of the gland the attached part is pulled off and may continue to live incorporated as a graft in the gastric duodenal or intestinal wall or mesentery The germinative cells, from which all the histologic units of the pancreas can develop are present in these buds or attached portions derived from the primitive anlage

Entire gastrolateathed tract opened in 114 cases,

This graft may find suitable environment and continue to live and develop into a small separate piece of pancreatic tusue consti tuting a pancreatic heterotopia with all the functions of the normal pancreas.

Lordy explained the presence of an acceasory pancreas by stating that it is due to persistence or incomplete regression of the left ventral anlage which is normally destined to atrophy Warthin described his concept of the origin of pancreatic beterotopia as follows

It is probable that accessory pancreatic tissue is formed from lateral budding of the rudimentary pancreatic ducts as they penetrate the intestinal wall, the mass of pan creatic tissue thus formed being snared off and carried by the longitudinal growth of the intestine either upward or downward.

Incidence The incidence of heterotopic pancreatic tissue not only at necropsy but at operation was studied from reports in the literature and from our own findings in the -urgical records and those of the Section on gic Anatomy of the Mayo Clinic. It

· that the incidence at necropsy varies

from 0 6 per cent to 5 6 per cent of soutme necropsies (Table IV) At operation heterotopic pancreatic tissue is found once in anproximately every 500 operations in the upper abdominal region.

There is a higher incidence of surgical cases in the fourth, fifth, and sixth decades of life than in other decades but the anomaly has been found in patients of all ages both young and old including infants and newly born. In our series the youngest patient was 4 months and the oldest patient was 64 years

Location We particularly endeavored to determine the usual and unusual locations of pancreatic heterotopias. The duodenum stomach, and jejunum are the most common sites with an incidence for the three sites of elmost 70 per cent 27 7 per cent for the duodenum, 25 5 per cent for the stomach and 15 9 per cent for the jejunum (Table III) All the other unusual locations are mentioned in Table III.

Morphology Heterotopic pancreatic tusue usually presents itself as a single, firm and, when visible yellowish (light yellow or cream color) or white opaque lobulated round, or irregular node with granular surface. The maximal diameter of the node is usually 1 to 4 centimeters. Its appearance is like that of the pancreas itself or of a salivary gland. Larger masses may be found (Fig 1)

The histologic picture of heterotopic pen creatic tissue is frequently the same as that of the pancreas itself with acini forming lobules with ducts and islands of Langerhans (Fig

"This table the incindes Vector's case, as well as one case of inlet cell denome without hypoglycemia and one case of inlet cell cystadenocarcinema with hypoglycemia, from the interators.

 There may however, be a lack of one or another histologic element of the normal pancreas.

In the majority of the cases reported as well as in our own cases the type of mu cosa directly overlying the heterotopic tissue is the same as the type of mucosa nor mally corresponding to that particular por ton of the gastrointestinal tract where the heterotopic pancreatic tissue is situated. We were not convinced of any direct relation continuity or transition between the glands and ducts of the mucosal epithelium and the actini and ducts of the heterotopic pancreatic

tissue The only possibility of indirect con nection would be by means of the excretory ducts of the heterotopic pancreatic tissue emptying into the lumen of the gastroin testinal tract through the ducts of the mu cosal epithelium. The commonest histologic location of heterotopic pancreatic tissue was found to be the submucosa alone with an in cidence of 53.8 per cent. The second most common type of involvement was infiltration between the longitudinal or circular muscular fibers or both, with an incidence of 33 per cent. The least common location was the seroesal surface (Table V)

\*Endre gestrobusednel tract opened to 514 cases. (Of clane stress.)

This "graft" may find suitable environment and continue to live and develop into a small separate piece of pancreatic tissue constituting a pancreatic heterotopia with all the functions of the normal pancreas.

Lordy explained the presence of an ac cessory pancreas by stating that it is due to persistence or incomplete regression of the left ventral anlage, which is normally destined to atrophy. Warthin described his concept of the origin of pancreatic heterotopia as follows. It is probable that accessory pancreatic tissue is formed from lateral building of the rudimentary pancreatic ducts as they penetrate the intestinal wall, the mass of pancreatic tissue thus formed being suared off and carried by the longitudinal growth of the intestine either upward or downward."

Incidence. The incidence of heterotopic pancreatic tissue not only at necropsy but at operation was studied from reports in the literature and from our own findings in the surgical records and those of the Section on Pathologic Anatomy of the Mayo Clinic. It is seen that the incidence at necropsy varies

from 0.6 per cent to 5 6 per cent of routine necropies (Table IV) At operation heterotopic pancreatic tissue is found once in approximately every 500 operations in the upper abdominal region.

There is a higher incidence of surgical cases in the fourth, fifth, and sixth decades of life than in other decades but the anomaly has been found in patients of all ages both young and old, including infants and newly born. In our series the youngest patient was 4 months and the oldest patient was 64 years of age.

Location We particularly endeavored to determine the usual and unusual locations of pancreatic heterotopias. The duodenum, stomach, and jejunum are the most common sites, with an middene for the three sites of almost 70 per cent 277 per cent for the duodenum, 25 5 per cent for the stomach, and 15 9 per cent for the jejunum (Table III) All the other unusual locations are mentioned in Table III.

Morphology Heterotopic panacratic tissue usually presents itself as a single firm and, when visible yellowish (light yellow or cream color) or white, opaque lobulated, round, or irregular node with granular surface. The maximal dismeter of the node is usually 1 to 4 centimeters. Its appearance is like that of the pancreas itself or of a salivary gland. Larger masses may be found (Fig. 1)

The histologic picture of heterotopic pan create tissue is frequently the same as that of the pancreas itself with acid forming lobules with ducts and islands of Langerhans (Fig

Physiology Special staining methods were utilized to determine whether or not heterotopic pancreatic tissue secretes enzymes. Mallory a (16,17) phosphotungstic acid he matoxylin stain was most satisfactory Histologic evidence of acinar function in our cases was present in 76 per cent. In these cases, refractile zymogen granules could be seen in the anex or base of the acinar cells or scattered all over inside these cells (Fig 3) An investigation was carried out in order to deter mine what influence this external secretion could have on the gastric acidity. As a result of the analysis of gastric contents in our cases. we cannot conclude that there is any significant deviation to indicate alkalinization of the gastric acidity brought about definitely by functioning heterotopic pancreatic tissue in the stomach wall. We did not carry out a histologic study with any special staining methods for types or functional activity of cells in the islands of Langerbans but we have no reason to disbelieve in the functional activity of the lalets of normal appearance in heterotopic pancreatic tissue We wonder whether heterotopic pancreatic tissue may not, to a certain crient, constitute a some what similar circumstance to a graft of a small fragment of pancreatic tissue.

It is of great practical importance, especally to the surgeon to note that hyper
insulnism and hypoglycemis have been
observed associated with extrapancrentic,
insulin-producing liste cell adenomas and
adenocaronnas (Table VI) If therefore
exploration is being carried out in a case of
hypoglycemia with definite 'Whipple's essential triad" and after a thorough search,
no tumor is found in the pancreas, the sur
even should look for beterotone pancreatic

tissue in its most common locations and also in such of the unusual sites as permit exploration

Pathology Pathologic changes have been found in heterotopic pancreatic tissue itself in the surrounding tissues or in both Heterotopic pancreatic tissue presents the same pathologic changes as the pancreas namely cysts pancreatitis hemorrhage necrosis, and neoplastic change (benign and malignant) Data on 3 cases of cyst formation in heterotopic pancreatic tissue are presented in Table I (Fig. 4). An investigation was carried out to determine the presence of dilatation of the ducts in pancreatic dystopias. The ducts were

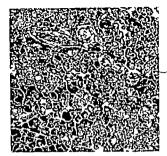

Fig. 2 Case 1 Table I Portion of a mass of heterotopic parcratic tissue measuring 3 5 by 3 by 1 5 centimeters on the posterior wall and lesser curvature of the stomach, showing acun and islands of Langerhans. Hematoxylin and cosin. X88.

found to be dilated in a large number of cases Both benign and malignant changes in heterotopic pancreatic tissue have been observed We feel that malignant change is more likely to take place in heterotopic pancreatic tissue than in the normally placed pancreas The heterotopic pancreatic tissue is not always completely formed and differentiated Both benign and malignant change would possibly be more likely to take place in an incompletely developed and less differentiated tissue in an aberrant location where it is subject to irritation than in a normal tissue in its iisual site. There have been cases in the literature in which the malignant change had its origin traced back to heterotopic pancreatic tissue It seems that there is little basis to believe in any connection between heterotopic pan creatic tissue and the histogenesis of car cmoids

Pathologic changes sometimes occur in the tissues adjacent to the heterotopic pancreatic tissue namely fat necrosis inflammation hemorrhage ulceration and diverticulum for mation. All the foregoing pathologic changes were studied fully especially ulceration of the mucosa overlying the dystopic pancreatic tissue which may be the cause of gastroduodenal ulcers in a small number of cases. In such cases conservative surgical treatment

Fig. 3 Case Table I Portion of a mass of heterotopic paracreatic tissue 1 th stomach wall Staining method hailtowys phosphoth gatic acid hematoxylin stain, ith oil immersion lens. 8 53. The individual symogra granules can be seen getomerated at the apex of the acids a cells.

is indicated namely simple local excision of the ulcer together with the underlying misplaced pancreatic tissue mass. Data on a cases are presented in Table I. Formation of a diverticulum brought about by heterotopic pancreatic tissue was studied data on a cases in which symptoms were caused by these lessons will be found in Table I.

Clinical significance In 25 (6) per cent) of the 41 authentic cases of pancreatic heterotopia the heterotopic pancreatic tissue was proved at operation to have been the only

Fig. 5 Case. Table I Mass of beterotope pancratile those measuring 3.5 by 3.5 commonters on the lesser curvature and posterior all of the stomach giving a rentgrenologic luster of an ovoid mass, in midporting a stomach, its malignant nature could not be excluded reentgenologically.

Fig. 4. Case 6, Table I Vlew from the serosal sid of portion of gastric wall, measuring 7,5 centimeters in diameter (excited—ith cautery) containing an intramural mass of heterotopic pancreaite tissue, measuring 3 by—centiscetters. Cytis can be seen grossly in the onocreatic tissue,

lesion the principal lesion or at least one of the lesions causative of symptoms for which the patient was submitted to surgical inter vention. Of the 25 authentic cases in which there were symptoms, it was seen that in o (36 per cent) the heterotopic pancreatic tissue was located in the gastric wall. The incidence in this location in all authentic cases, with or without symptoms was 31 7 per cent. In 6 (24 per cent) of the cases in which there were symptoms the location was in the duodenal wall. The incidence in this location in all authentic cases was 24.4 per cent. There were no cases with felunal location presenting symptoms but the incidence in this location in the authentic cases without symptoms was approximately to per cent (Tables VII and VIII) For the cases in which heterotopic nancreatic tissue occurred in other locations see Table III In most of the cases of pancreatic heterotopia in which there were symptoms, the location was either gastric or duode nal Proportionately the cases of beterotopia with gastric location contribute more than the ones with duodenal location to the number of cases with symptoms. In 13 cases reviewed there was persistence of symptoms possibly because of failure to remove a supposed pan creatic heterotopia at operation.

Symptomatology There is no single symptom complex for pancreatic heterotopia. The symptoms, of course vary according to the

Fig. 6. Case 1 Table I Mass of heterotopic pancreatic tissue measuring 3 5 by 3 by 1 5 centimeters on the lesser curvature and posterio wall of the stomach. The patient gave a history simulating that of duodenal ulcer and a loss of weight. The tumor was mistaken clinically roentgenologically and at operation for an adenocardnoma of the stomach. The tumor had been sectioned for examination when this picture was taken

different locations in which heterotopic pan creatic tissue may be found. The symptoms produced however are generally similar to those produced by gastroduodenal lesions namely symptoms of gastric ulcer duodenal ulcer pylonic obstruction cholecystitis obstruction of the common duct, chronic or acute appendicitis or indeterminate digestive symptoms The group of authentic cases in which there were symptoms was reviewed in subgroups divided according to location and the complication or disturbance that the anomaly caused There were 10 authentic cases of pancreatic heterotopia with a gastric location and presenting symptoms which were caused by the heterotopic pancreatic tissue as proved by the relief of the symptoms after its removal Data on 6 cases are presented in Table I (Figs. 5 6 7 8 and 9) There were 7 authentic cases of pancreatic heterotopia with duodenal location and presenting symptoms

Fig. 7 Case r Table I Heterotopic pancreatic these mass, showing pancreatic tissue extending between the muscular bundles. Grossly the tumor seemed to infiltrate the muscular coat of the stomach. Hematoxyiin and coan. Xro.

which were caused by the heterotopic pan creatic tissue as proved by the relief of symptoms after its removal in practically all the cases Data on 3 cases are presented in Table I (Fig. 10)

Among our 10 cases of pancreatic heterotopia with a gastric location there was 1 case in which pyloric obstruction was observed

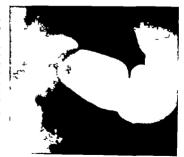

Fig 8. Case : Table I Gastric nodule of heterotopic pancrealite tissue : 5 centimeters in diameter producing a filling defect near the greater curvature just proxumal to the pylorus it appeared like a lefomyoma growly at operation

Fig 9 Case 7 Table I Nodule of heterotopic pan creatic tissue measuring 8 millimeters in diameter in the submucosa of th posterior all of the prepyloric region of the stomach. The overlying gastric mucosa is pitted.

Data on this case are presented in Table I (Figs. 11 and 12) Seventeen cases of pyloric stenosus which were secondary to the presence of heterotopic pancreatic tissue were collected by kneg from the medical literature in 1030 and published in 1041. We found in the literature s additional cases of heterotopic pancreatic tissue causing nyloric obstruction from the time of Knegs review in 1930 up until March, 1944 Krieg mentioned a group of 23 cases of Poppi's series which he interpreted as having been produced by local spasm of the intestinal wall. In his opinion the difference between the cases of stenosis and those of spasm is that of time and the degree of irritation.

Hypertrophy of the muscular coat was evidenced grossly and microscopically in 11 out of 19 authentic cases of our series of pan creatic heterotopia in the gastrointestinal tract. In our series of authentic cases, there were 2 cases of Meckels diverticulum containing heterotopic paneratic tissue. Data on

Fig. 10 Case 3 Table I. Nod le of heterotopic pan create them, measuring 1 5 by by 0 5 centinater in the anterior all of doodenum immediately below pyloris. The mass looked like fibroms grossly 1 operation.

a case of ileal intussusception brought about by an ileal diverticulum containing pancreatic tissue will be found in Table I Data on a case of pancreatic heterotopia in the wall of the gallbladder are presented. This case is of interest in the light of Coln and Doubllet s studies on the clinical significance of pan creatic reflux. Data on a case of obstruction of the common duct caused by heterotopic pancreatic tissue are presented in Table I The possibility of duodenal adenocarcinoma arising in dystopic pancreatic tissue in the ampulla of Vater and in the papilla of Santorini is suggested. A study of the pathogenesis of the disturbances and symptoms caused by heterotopic pancreatic tissue was made The pathologic changes have an influence on the production of symptoms.

Diagnosis The clinical, the roentgenologic the operative and the pathologic diagnosis of pancreatic heterotopia were reviewed. Of the cases in which the heterotopic tissue was in a gastric location the diagnosis of a benign

Fig. 11. Case 8, Table I. Annular mass of heterotopic parcriatic tissue on the serosal surface of the pyloric ring. The roentgemologic report was as follows: Annular lesion involving pylorus, prepyloric area and hase of duodenum, shallow ulceration. Impossible to exclude malignancy.

tumor was made in 50 per cent of ulcer in 20 per cent, and of malignant tumor in 20 per cent. The mass was missed in 10 per cent. In only 1 of the cases in which the location was duodenal was the diagnosis of duodenal tumor made. In all the others the roentgenologic diagnosis of duodenal ulcer was made although in only I was an ulcer actually present. The preciseness of the roentgenologists diagnosis of gastric polyps may be seen from his reports in 6 of our cases in which the masses were of relatively minute propor tions The diagnosis of a gastric or duodenal polyp is the nearest that one can actually get to the precise and final diagnosis made by the pathologist, although in 3 cases of our series the exact nature of the mass was suspected Apparently analysis of gastric contents is of no avail in determining possible alkalinity or reduced acadity of gastric contents due to alkalınızatıon of the gastric juice from pan creatic secretion flowing from heterotopic pancreatic tissue although this possibility should be kept in mind. Gastroscopy might

Fig. 12 Case 8, Table I. Specimen 12 centimeters of stomach and 15 centimeters of deodenium Heterotogic pancreatic tissue forming an annular mass, 3 centimeters in diameter on the serosal surface of the pylone nag. The tumor in the picture is included between the points of the two arrows. It was causing pyloric obstruction and loss of weight clinically roentgenologically and grossly at opera tion it was mistaken for an adenocarcinoms of the stomach

possibly be an aid in the diagnosis by confirm ing the roentgenologic finding or by revealing the tumor to be intramural covered by nor mal mucosa and not ulcerated as in gastric carcinoma When visible on the serosal surface a pancreatic beterotopia is grossly recognizable but there should always be a confirmative diagnosis by the pathologist In 18 surgical cases of pancreatic heterotopia in which a notation was made of the surgeon a impression from gross examination we reviewed the operative diagnosis made prior to the pathologist s report. In approximately 20 per cent the pancreatic heterotopia gave the impression of a malignant lesion. In 50 per cent the diagnosis of a benign lesion was made In a little more than 22 per cent the nature of the mass was recognized correctly as being

Exploration of the properties of the Explorations of the recommon duct was performed in ... case

heterotopic pancreatic tissue. The pathol ogists diagnosis based on examination of frozen sections at the time of operation is essential The correct diagnosis was promptly made in practically all the cases.

Surgical treatment There are two circum stances in which a pancreatic heterotopia may be found at exploration at is either causative of symptoms or it is only an incidental find ing In Table IX we listed the operative procedures performed in 25 cases of our series of pancreatic heterotopia that were clinically significant. In no case was persistence or recurrence of symptoms observed following the complete radical or conservative removal of the pancreatic beterotopia when this lesion was the only cause of the complication and referred symptoms. In some of the cases of our senes a more conservative operative procedure rather than gastrectomy could have been performed probably with equally good final results had it been possible for the surveon to know that he was dealing with a benum lesson. In only a case in our series did a patient die from a complication associated with a pancreatic heterotopia namely ileal intussusception

When the pancreatic heterotopia is located in the stomach or duodenum simple local excision when feasible is sufficient to bring about relief of symptoms. At times careful duodenal reconstruction or pyloroplasty may have to be carried out. Since as is shown by the abstracts of the case records, in most instances a roentgenologic diagnosis of ulcer tumor carcinoma, or polyp was made preoperatively it is understandable why in 10 instances partial gastrectomy was chosen by the surgeon as the procedure to be performed.

It would be difficult to tell by palpation the nature of the lesion and blops, of gastric lesions is at best frequently indeterminate. Therefore by and large with carcinoms so common in the stomach and pancreatic he terotopia so uncommon it would be to the patient's best interest to elect gastne resection Frequently one of the modifications of the Billroth I operation would be possible and indicated when the lesion is found in the lower third of the stomach. In higher lessons a Polya operation or one of its modifications would be suitable

In the presence of a diverticulum associated with heterotopic pancreatic tissue removal of the diverticulum together with the heterotonic tissue is indicated with simple local excision alone or possibly with pyloroplasty or duodenal reconstruction. In the presence of muscular hypertrophy possibly associated with pylone stenosis, excision and pyloroplasty are indicated

Whenever pathologic changes are en countered in other organs with the presence of a pancreatic heterotopia and the former seem to have more to do with the nationt a symptoms than the latter the surreon should not underestimate the potentiality for production of symptoms or actual present clinical significance of the pancreatic heterotopia, complete removal of which should be carried out. The operative procedure advised for pancreatic beterotopia in locations other than the stomach and duodenum is complete but simple extirpation but no generalizations can be made so varied are the locations. One has to depend on one a surgical judgment in the particular case. As far as the pancreatic heterotopia is concerned one can be as conservative as possible. In several of our surgi cal cases of clinically significant pancreatic heterotopia operation had been performed for some other condition prior to admission of the patient to the Mavo Clinic and at a time when the heterotopic pancreatic tissue was not clinically significant. If the heterotopic tissue had been removed at this time the later operation for its removal could have been avoided Whenever heterotopic pancreatic tissue is found in the stomach or duodenum incidentally during the course of an operation

for some other surgical lesion its excision is indicated to avoid future trouble unless the risk of the procedure outweighs the ad vantages of removal A jejunal pancreatic heterotopia found incidentally during the course of an operation for some other condition may be left undisturbed with a fair chance that no complications will be observed subsequently unless such pathologic changes are present that there is a question as to either its present or its future clinical significance The same general rule as the aforementioned one would hold true for pancreatic heterotopia in other locations, although surgical judgment for the particular location varies

#### SUMMARY AND CONCLUSIONS

There are approximately 470 recorded cases of pancreatic heterotopia Pancreatic heterotopia is observed fairly frequently at routine necropsies We found an incidence of 1 case of pancreatic heterotopia in approximately every 500 operations in the upper abdominal region The incidence of pancreatic heterotopia is highest in the fourth fifth and sixth decades of life

The ratio of males to females is almost 3 to The most common location is in the stom. ach duodenum and jejunum where the incidence is almost 70 per cent. In the ma jority of the cases the mass of heterotopic pancreatic tissue is single and its diameter usually varies from 1 to 4 centimeters

The histologic picture of heterotopic pan creatic tissue is frequently the same as that of the pancreas itself The commonest histologic location of heterotopic pancreatic tissue in our series was the submucosa alone. There frequently is intermuscular infiltration the vast majority of the cases there is histologic evidence of acinar function There is no apparent change in the results of analysis of gastric contents associated with a pancreatic heterotopia

Hypoglycemia and hyperinsulinism have been observed in association with heterotopic pancreatic tissue presenting both benign and malignant change in its insular portion. If exploration is being carried out in a case of hypoglycemia with definite Whipple's es sential triad and after a thorough search no tumor is found in the pancreas the surgeon should search for heterotopic pancreatic tissue in its most common locations and also in the unusual sites that are capable of ex-Both adenomas and adenocar ploration cinomas of islet cell type may be present without clinical evidence of hypoglycemia

Heterotopic pancreatic tissue presents the same pathologic changes as the pancreas itself. In many cases the ducts are found dilated Malignant change is more likely to take place in heterotopic pancreatic tissue than in the pancreas proper Pancreatic heterotopia may be the cause of several types of pathologic changes in the adjacent tissues namely fat necrosis inflammation ulcera tion hemorrhage necrosis and formation of a diverticulum

In a high percentage of surgical cases of pancreatic heterotopia (61 per cent of our cases) the heterotopia is found to be of clinical significance The location is usually gastric or duodenal Some of the rare adenocar cinomas of the duodenum may have had their origin in heterotopic pancreatic tissue either in the ampulla of Vater or in the papilla of San The syndromes presented by a pancreatic heterotopia are generally those of gastric or duodenal ulceration cholecystic disease or indeterminate digestive symptoms

The pathologic diagnosis with frozen sec tion technique at the time of operation is of mestimable value A mass of heterotopic pancreatic tissue can be mistaken for a ma lignant growth both roentgenologically and at operation with a consequent unnecessary operation. When the pancreatic heterotopia is clinically significant its simple excision when feasible is entirely sufficient for complete relief of symptoms. When found in cidentally at operation its removal is indicated in the majority of cases.

### SECONDARY SUTURE OF WAR WOUNDS

## A Study of Methods and Results in an Overseas General Hospital

KNOWLES B LAWRENCE, M D., F.A.C.S., and SOMERS H STURGIS M.D F.A.C.S.

Roston Magaschusetta

THE success of the U S Army Med real Corps policy of early débridement of wounds without primary suture in preventing serious infection was dem onstrated repeatedly during World War II It was equally well known that secondary heal ing of such débrided wounds by granulation and epithelization often consumed several months. Painful and disabling cicatrices osteomyelitis, stiff joints and muscle atrophy were frequent complications of wounds allowed to heal by second intention. Psychoneurosis developed or aggravated during long hospitali zation rendered many soldiers unfit for further combat duty For the first 2 years after Pearl Harbor the tremendous wastes in man power and in hospital care resulting from such a slow healing were serious hindrances to the war effort.

The obvious answer to these problems was to effect closure of débrided wounds as early as consistent with safety In World War I pri mary suture was practiced sometimes on selected wounds not more than 12 hours old (5) The percentage of successful healing in several series of primarily sutured wounds including a few joint wounds was excellent (from 66 to 04 per cent) but there was also a significant mor tality rate. It was concluded as a result of those experiences that the use of the primary suture after débridement should be restricted quiet periods in the fighting when the wounded patient could be kept in one hospital until healing was assured. The decision to close the rest depended largely on the reports from routine culture and smear taken at the daily dressing Delayed primary suturing of wounds free from hemolytic streptococci. within the first s days was distinguished from the secondary suture' of all later closures in which inversion of skin edges and a granula

Formerly members of the Surgical Service, 6th General Hospital, U. S. Army

ting base had developed. In both delayed primary and secondary closures a miscella neous assortment of antiseptics had been previously applied to combat the nearly omni present infection. Reported results in small series of cases varied from 66 to 88 per cent of 'success. (r. 5). In general the methods of early closure of wounds during World War I seemed either too narrow in selection of cases or too cumbersome in practice to be applicable to large numbers of wounds encountered under average conditions of combat.

Experiences reported from the Republican army in the Spanish Civil War obscured the issue in a sense for, there emphasis was placed on the plaster encasement treatment of serious extremity wounds (7). The primary missions of reducing fatality rates and obtaining rea sonable healing of fractures despite unfavor able tactical attuations were accomplished by this treatment. That better and more rapid healing might be obtained by early closures of such wounds in communication zone hospitals and with the help of modern chemotherapeutic agents was not envisaged at that time

The use of chemotherapy in conjunction with radical débridement in World War II seemed to change the pathology of war wounds The majority remained grossly as clean as any other surgical wounds, if infection was not introduced by changing the dressing at least for a week or 10 days following debridement In overseas base hospitals surgeons guided by this finding tried secondarily suturing these wounds during this initial period when they were 'clean' By 1944 this procedure was being performed routinely during the first 10 days after débridement in many U.S. Army hospitals of the Mediterranean Theater 1 Re sults were gratifyingly good In June 1044 Kirtley and Trabue reported 92 7 per cent

Ses Circular letter No. 16, The Surgeon, North African Theater of Operations, United States Army April 19 1944. successful healing in one group of 217 de layed primary sutures, and only 3 infected wounds in another group of 30 cases studied in detail. In the latter group 71 individual wounds were sutured 4 to 5 days after wounding. Wilson obtained healing without infection in 85 per cent of 224 wounds secondarily satured when less than 10 days old. In wounds satured after 10 days the primary healing rate was reduced to 38 per cent. Wilson 5 study was based on 305 total wounds in 209 patients. The results in both series are colored somewhat by the fact that compound fracture cases apparently were not included.

The work of British surgeons on this important subject as reported to the Congress of Central Mediterranean Force Army Surgeons, Rome Italy February 1045 is of special in terest. After a somewhat longer period of participation in the war the British were fully aware of the advantages of early closure of wounds. Their efforts as described at that meeting were being directed toward the improvement of results in such wound handling chiefly by the local use of chemotherapeutic agents. Murray reported that or per cent of 500 flesh wounds treated locally with a penicillin powder at time of suture healed successfully after delayed primary suture! in contrast to 75 per cent successful healing in 220 proflavine treated wounds. In a paper entitled Early Closure of Compound Frac tures at the same congress Hendry reported 60 per cent of his cases with complete healing of the skin over major fractures of long bones within 6 weeks after delayed primary suture

Secondary closure was performed on the wounds of approximately 2200 patients at the 6th General Hospital situated near Rome, Italy during July August, and September of 1044. The present report is based chiefly on a series of 1110 of these patients with more than 2700 individual wounds. Most of the balance consisted of a number of patients operated upon during this period which could not be included solely because the press of work at times made it impossible to obtain and record the necessary data. At least 100 patients were evacuated to the rear to create bed space be fore healing results could be evaluated. Oute

a few cases, in which wounds were limited to amputations or to wounds of the fingers, toes or face were excluded also because they represented a different sort of surgical problem. Aside from these specific omissions the series was unselected and included various types of soft tissue wounds as well as those associated with compound fractures. Thirty different surgeons operating on these patients used their own judgment in carrying out the details of the general pollcy

#### GENERAL POLICY

A great influx of recent casualties arriving from forward hospitals with wounds already debrided made necessary the adoption of mass production methods of surgical man agement. This consisted principally of a systematic performance of secondary auturing in the early clean period within a week or ro days after debridement.

Guided by our own previous experience and reports from other hospitals, it was the policy to leave the dressings unchanged until the patient s arrival in the operating room. How ever a few wounds required preoperative inspection because of unexplained fever pain excessive drainage or hemorrhage. In general this method represented a vast saving in time materials and discomfort to the patient over the daily dressing regimen of World War I Many patients received sulfadiazine by mouth, and this was often continued for several days after operation. The use of penicillin paren terally was not routine and was usually restricted to severe compound fractures wounds into joints, and growly infected wounds. Transfusions of blood and plasma, vitamins and other supportive treatment were used as indicated. Most surgeons preferred a time interval of at least 48 hours between admission and secondary suture to allow for rest and observation

In the group of cases here studied of per cent were admitted to this hospital in time to be scheduled for secondary closure before the tenth day following their débridement. Occa sionally secondary closure was contraindicated by the condition of the patient or his wound. It was soon noted that the clinical appearance of the wound on the fifth or sixth day after débridement suggested that this was the most favorable time for suturing

On first inspection of these wounds in the operating room we were surprised at the small percentage which seemed unsuitable for closure because of gross aigns of necrosis. In a series of over 300 wounds personally observed by the authors, this was less than 5 per cent, and testified to the excellent results from débridement and chemotherapy usually peni cillin at forward hospitals. Culturing of wounds for determination of bacterial flora was impractical as a routine procedure.1 Wounds containing thin purulent exudate, with, at times slight reddening of skin at margins and turnidity of tissues proved to be trouble makers. Such wounds were very ant to become septic and break down if su tured in that condition and did much better after preliminary treatment for 24 hours or more with wet dressings of which the most effective seemed to be penicillin solution (500 or 1000 units to 1 c.c.) Patches of fibrin adherent to otherwise fairly dry and innocent looking wounds usually did not deter healing A number of wounds, though clean were of such a large size or so located that they could not be closed completely by secondary suturing. In some the unsutured part was left to heal spontaneously In others this area was covered with a split thickness skin graft immediately or at a later date. The longest wound measured 70 centimeters extending from the lateral aspect of the hip to the knee. It healed satisfactorily after secondary su turing. The greatest number of wounds in one patient was one hundred

#### TECHNICAL ASPECTS OF SECONDARY SUTURING

Anethesia Intravenous sodium pentothal was the most commonly used anesthetic agent. There were no deaths attributable to pentothal in this series. Novocain locally was used in about one quarter of the cases. Infiltration of subcutaneous tissue from the wound surface seemed simpler and caused less discomfort to the patient than block anesthesia through the intact skin

The wiscens of this decision to oralt routine wound cultures was confirmed later by the work of bently and Thomson who found that only ap per cent of series of a greaty clear wounds contained or thought bectral and that satisfactory beating was obtained after secondary suturing in 5 per cent of wran these "latested wounds."

Surgical technique Accurate approxima tion of the entire depth of the wound without excessive tension was the primary objective of the operation. It was felt that the less cutting or surgical manipulation of any kind the less risk there would be of breaking through the natural defenses against infection that had been mobilized about the wound edges in the preceding days. Wounds more than a week old, however generally require freshening or freeing up of the margins to obtain apposition of the skin edges without inversion Wounds over large muscle bellies, as in the thigh, but tocks, or arm, often presented a problem in closure unique to war injuries. The swelling of injured muscles at times produces wide retraction of wound margins. Where there is no significant skin loss the degree of tension required to close these wounds accurately reflects the amount of edema to be reduced Therefore, marked tension in the closure of these particular wounds is not only tolerated but proportionately necessary to relieve lymphostasis and congestion and undermin ing the edges to avoid this tension in such wounds is undesirable. Where there was major. skin loss extensive undercutting was resorted to without hesitation in order to close the would. Advancement and rotation of contig uous akin flaps occasionally permitted closure of wounds in which even wide undermining did not accomplish this result. Due to expemence with flexion deformities and recurrent breakdown of scars which were situated ver tically over joints, particularly in the popliteal space we utilized these maneuvers to obtain more nearly transversely placed suture lines in such areas. Black alk was the most commonly used suture material, employed sometimes in conjunction with silkworm gut. The latter seemed to cause less tissue reaction and

cutting through when under tension The deep fascia was approximated as a separate layer in a few cases. Several instances of post operative wound infection were seen with extrusion of nonabsorbable sutures however, and therefore buried sutures were avoided as a general policy. If the edges of aponeurosis or fascia are included in the deep bites of vertical mattress sutures, solid healing will be obtained in most cases. Of the few postoperative mus-

successful healing in one group of 217 delayed primary sutures, and only 3 infected wounds in another group of 30 cases studied in detail. In the latter group 71 individual wounds were sutured 4 to 5 days after wound ing. Wilson obtained healing without infection in 85 per cent of 224 wounds secondarily sutured when less than 10 days old. In wounds sutured after 10 days the primary healing rate was reduced to 38 per cent. Wilson s study was based on 305 total wounds in 200 patients. The results in both series are colored some what by the fact that compound fracture cases apparently were not included.

The work of British surgeons on this important subject as reported to the Congress of Central Mediterranean Force Army Surgeons, Rome, Italy February 1945 is of special in terest. # TECHNICAL ASPECTS OF SECONDARY SUTURING

Anesthesia Intravenous sodium pentothal was the most commonly used anesthetic agent. There were no deaths attributable to pentothal in this series. Novocaln locally was used in about one quarter of the cases. Infiltration of subcutaneous tissue from the wound sur face seemed simpler and caused less discomfort to the patient than block anesthesia through the intact skin general policy. If the edges of aponeurosis or

this attention of the first process of the state of the s

tion of the entire depth of the wound without excessive tension was the primary objective of the operation It was felt that the less cutting or surgical manipulation of any kind the less risk there would be of breaking through the natural defenses against infection that had been mobilized about the wound edges in the preceding days Wounds more than a week old however, generally require freshening or freeing up of the margins to obtain apposition of the skin edges without inversion Wounds over large muscle bellies as in the thigh but tooks or arm, often presented a problem in closure unique to war injuries. The swelling of injured muscles at times produces wide retraction of wound margins Where there is no significant skin loss the degree of tension required to close these wounds accurately reflects the amount of edema to be reduced Therefore marked tension in the closure of these particular wounds is not only tolerated but proportionately necessary to relieve lymphostasis and congestion and undermin ing the edges to avoid this tension in such wounds is undesirable Where there was major skin loss extensive undercutting was resorted to without hesitation in order to close the wound Advancement and rotation of contig uous akın flaps occasionally permitted closure of wounds in which even wide undermining did not accomplish this result. Due to expe rience with flexion deformities and recurrent breakdown of scars which were situated ver tically over joints particularly in the popliteal space we utilized these maneuvers to obtain more nearly transversely placed suture lines in such areas. Black silk was the most com monly used suture material employed some times in conjunction with silkworm gut The latter seemed to cause less tissue reaction and cutting through when under tension The deep fascia was approximated as a separate layer in a few cases Several instances of post operative wound infection were seen with extrusion of nonabsorbable sutures however, and therefore buried sutures were avoided as a

fascia are included in the deep bites of vertical mattress sutures solid healing will be obtained in most cases Of the few postoperative mus

cle hernias observed only an occasional one has been symptomatic.

At first many deep wounds were drained at the time of secondary suture because of poten tial dead space retained blood clot or border line infection. With more experience this was found rarely necessary except in cases of compound fractures of the larger bones. Depen dent stab wound drainage employing soft Penrose tubing was found preferable to draining through the suture line. The drains usually were removed within 1 to 4 days.

The wound surfaces were dusted with sul fanilamide powder in some cases but only one of the surgeons felt this was sufficiently valu

able to employ it routinely

Casts or plaster solints were applied in many of the extremity wounds involving soft tissues only. After observing the breakdown of several of the unsplinted wounds near joints we were convinced that this should be practiced more widely

#### POSTOPERATIVE MANAGEMENT

It appears to be necessary to retain stitches in a secondarily sutured wound longer than is usually necessary in a primarily sutured wound. In the absence of infection the stitches were generally removed in from 10 to 14 days.

Mobilization of joints and muscle training were practiced as early as tissue reaction per mitted in many cases even before wounds were completely healed Experience showed that wounds of the lower extremities, however healed far more promptly if patients were kept off their feet until healing was complete.

#### RESULTS

Percentage of healing For purposes of detailed study the healing of these wounds was classified as primary delayed primary or secondary The meaning of primary heal ing is obvious. In certain wounds localized eversion of skin edges mild stitch reaction persistence of the drain sinus or delayed heal ing where cruciate incision corners had been brought together did not represent perfect primary healing. The end result though delayed a few days hardly differed from that in primary healing however. We called this delayed primary" healing Primary and

delayed primary healing together constituted satisfactory healing When definite infec tion and separation or breakdown of the suture line occurred the result was called unsatisfactors in so far as value of the operation of secondary suture was concerned 1

Calculated on the above basis the overall healing results in the series were as follows For 1110 cases the healing was either primary or delayed primary (and therefore satisfac tory ) in 037 or 84.4 per cent in 173 or 15 6 per cent the healing was unsatisfactory. In an unselected group of about half the cases (605 cases) the effect of an associated compound fracture was noted. Serious compound frac tures were present in 110 of these. There were incomplete or chip fractures in 20 other cases In 85 or 77 3 per cent of the 110 major frac tures, the secondary closures healed satisfac torily Although lower than the satisfactory" percentage for the total we feel this is an acceptable showing for the large and complicated wounds of this type. Twenty three of these involved humerus or femur 18 of the compound wounds healed satisfactorily" in this small group and only 5 were unsatis There were no cases of infection or gangrene leading to amputation attributable solely to the closure of the wound and no deaths. Secondary suturing of wounds complicated by compound fractures, then was found to be a sale and justifiable procedure.

Oblimum time for secondary suture Table I shows the ratio of satisfactory to unsatisfac tory healing after secondary suture by days from date of wounding. The ratio of virtually 10 1 for cases operated upon the 6th day after wounding is the best showing for any of the larger groups. After the 6th day the ratio becomes definitely less favorable. Since the delay in debridement of the wounds averaged nearly 24 hours, the choice of 5 days as the optimum time from débridement to secondary suture appears to be vindicated statistically in this series of cases.

Choice of anesthesia in secondary suture Local anesthesia was used in 243 cases with satisfactory healing in 215 or 884 per cent unsatisfactory in 28 or 11 6 per cent. General

Fig. all the tables in this report, the figures refer to came and not to individual seconds. Where there were malipie seconds, if only one brids down, the came was labelled. onestarfactory

anesthesia was used in 867 cases with satisfactory results in 722 or 83 3 per cent unsatis factory in 145 or 16 7 per cent Local novocain was used generally in the smaller wounds and only where there was no obvious sepsis. Keeping this method of selection in mind it is clear that in this series the use of infiltration anes thesia did not increase the postoperative rate of infection or adversely affect the percentage of satisfactory healing. We know of no in stance of significant wound infection attributable solely to the use of local anesthesia in the closure.

The figures for disposition Disposition after secondary suture in this hospital were available for 1204 patients as follows There was a salvage rate of approximately 72 per cent of the men for General Service within an average time of only 6 weeks after wounding The disposition of a great majority of the 18 1 per cent discharged for evacuation to the Zone of the Interior (United States) was determined by the presence of fractures nerve injuries amputations or other conditions not directly affecting the healing of their wounds A higher percentage of the Limited Service cases were so reclassified chiefly because of wound disability but other conditions or complications also dictated this disposition in many cases

#### OBSERVATIONS

We feel that the healing results obtained in this large series of war wounds can be improved with more experience. Limitations as well as possibilities of secondary suture have been learned. Some of the older or slightly infected wounds might have healed better after application of hot compresses or antiseptic dressings for a few days before suturing. The more experienced use of the various plastic surgical maneuvers to obtain approximation of skin edges without tension more thorough splin ting of wounds near joints, and enforced bed rest during healing of leg wounds all should increase the percentage of satisfactory results. As noted above (2) British Army surgeons found that the local application of penicillin to the wounds increased their ratio of successful healing after secondary suture. They did not have a comparable series of wound cases with systemic penicillin treatment but showed

that wound infection sometimes developed despite intramuscular penicillin in usual doses. Further reports may clarify this subject

Secondary suturing may be applied in peace-time traumatic surgery The majority of such wounds whether due to vehicle and industrial accidents or injury by firearms explosives or other means will prove amen able to immediate primary suture after thorough débridement. In the light of present knowledge the administration of penicillin systemically would be indicated in all but minor wounds. A few wounds with excessive contamination marked tissue destruction or prolonged time lag between injury and treat ment will be more safely handled however by delayed suture. We would suggest cultur ing a wound of this type at the time of debridement Sulfanilamide or penicillin' could be applied topically if the surgeon desired and an occlusive dressing applied. The first change of this dressing should be made in the operating room on the fourth or fifth day If the wound appeared grossly clean and the first culture had grown no hemolytic streptococcus secondary suture would be indicated at that time. If however the wound appeared septic

\*Some British Army surgeons favor penkillin-salfathiansle powder for this use and frost the wound surface thoroughly

or the culture revealed hemolytic streptococcus suture should be deferred for at least 2 days. Wet dressings perhaps with peni cillin solution, should then be applied frequently until the wound becomes sufficiently clean to tolerate suturing Such a routine should result in satisfactory healing in a very high percentage of cases.

#### SIDIMARY

The results of secondary suturing of a series of wounds at an overseas General Hospital during World War II have been analyzed.

In 937 84.4 per cent, of 1110 cases, satisfactors healing was obtained as a result of this procedure

It was found to be safe and generally satisfactors to suture secondarily those wounds

associated with compound fractures. Details of technique and management related to secondary suture are discussed

It was possible to return 71 o per cent of the men to general service 100 per cent were reclassified to limited service and 18 1 per cent were discharged from this hospital for evacuation to the Zone of Interior

The application of this method of handling to certain peacetime wounds is recommended.

# POSTCAVAL URETER, WITH DESCRIPTION OF A NEW OPERATION FOR ITS CORRECTION

#### OSWALD S LOWSLEY AB M.D F.A.C.S F.I C.S New York, New York

THE location of the right ureter behind the vena cava instead of over lying it, is a very rare anomaly, only 33 cases having been reported in medical literature to date. Even rarer is cor rective surgical treatment of the condition only a such attempts having been reported previous to the one presented here 1

In the present case a new operation was utilized which appears to have merit. It will

therefore be described in detail

#### REVIEW OF THE LITERATURE

Hochstetter, in 1802, was the first to describe a case of postcaval ureter in man this was in an infant a few weeks old and was discovered during routine dissection

Pick and Anson tabulated 28 cases up to 1940 including one of their own Five more have been added since one each by Harbach (1040) Harrill (1041) DeCarlo (1041) Gru enwald and Surks (1943) and Wilson and Herzlich (1944) The author's case makes the thirty fourth to be reported 2

Of these 34 cases 22 were diagnosed at post mortem examination or laboratory dissection 11 (including ours) at operation, and only 1

before operation

All but 3 of the 34 patients were adults. Of these 3 cases, all discovered at routine dissection, one was in a stillborn infant, another in an infant a few weeks old and the third in a year old child.

Twenty five were males 7 were females and in 2 cases the sex was not given. It has

From the Department of Urokey (James Bochanan Brady Foundation) of the New York Hospital.

The necessary funds for this windy were furnished by the Alfred Busiel Research Fund.

\*\*Commander Moody of the U.S.N. Horpital at St. Albana, N.Y. has notified the author of a sixth patient operated upon by him recently if its swerred the urrier and made an end-to-end anastomosis over the vena cava

assimonous ever the vens cave.

Since this articl was submitted, as additional case has been reported by Doctors L. F. Greene and W. M. Keurss of the Mayo. Clmic. This was the second cave in which the distroots was made before operation and the fifth case in which playle repair was done. The urreit was severed and annatomosed in its upper portion.

been suggested that the fact that males out number females by more than 3 to 1 in the reported cases may be accounted for by the greater number of male bodies that come to the dissection room and the postmortem table (where a majority of these cases were discovered) Of the II patients operated upon 7 were males and 4 females Although a small group, this would seem to bear out the belief that the anomaly is more common in males.

Postcaval ureter may take several forms. The most common form is unilateral per sistence of the posterior cardinal vein (observed on the right side only) the postrenal segment of this vein forming the postcava Most of the reported cases are of this type In 5 cases (Rotter Uebelhoer Adachi 2, and Harrill) there was double postrenal vena cava. one on the right and one on the left side the ureter passing behind the corresponding vein In only 1 case (Gladstone 1905) was there bilateral involvement. This case a stillborn acardiac infant, showed bilateral postcaval ureters (double postrenal vena cava, one on each side of the aorta with each preter passing behind its respective vein)

#### EMBRYOLOGICAL CONSIDERATIONS

Present day opinion unanimously ascribes the anomaly to the embryonic vascular system rather than the unnary Faulty development of the inferior vena cava and not maldevelopment of the ureter is the etiological factor responsible. In most of the reported cases the preureteric vena cava was associated with other anomalies of the retroperitoneal veins

All later attempts at explaining the origin of anomalous retroperatoneal veins are based on the embryological work of McClure and Butler (1925) and Gruenwald (1938) Ran dall and Campbell Pick and Anson and Gruenwald and Surks have gone thoroughly into the embryology of postcaval ureter and the reader is referred to their papers

Briefly in the development of the embryo three bilaterally symmetrical pairs of veins appear in the lumbar region the posterior cardinals (lateral) the subcardinals (ventral) and the supracardinals (dorsal) Numerous anastomoses between these form venous rings.

Quoting from Pick and Anson

"During fetal life the permanent kidney (meta nephros) having developed in the pelvis, ascends to the upper lumber level, passing through a ring of venous channels (perimetanephric or periureteral ring) The ventral limb of the ring is formed by the lumbar division of the postcardinal vein and the subcardino-postcardinal anastomosis (McClure and Butler and sacrocardinal vein according to Green wald) The dorsal limb is a derivative of the lumbar division of the supracardinal vein and the subcar dino-supracardinal anastomosis (McClure and But ler or sacrocardinal vein of Greenwald)

"Normally the postrenal portion of the inferior vena cava arises from the dorsal limb of the peri metanephric ring the ureter thereby being placed in an antecaval position. But, in the anomalous ar rangement of the areter and vessel, one of the fol lowing developmental alterations occurs (r) the ventral rather than the dorsal limb persists the preter then being postcaval (a) the dorsal limb fails to arise at all-with similar results (3) both limbs are present and persistent—the ureter passing be

tween cavae

Most writers on the genesis of this anomaly agree that it forms from that limb of the em bryonic perimetanephric ring which normally degenerates that is, according to McClure and Butler the cardinal vein. However two later writers (Gruenwald and Surks) after going very extensively into the embryology express the opinion that the preureteric vena cava is a derivative of the subcardinal rather than the cardinal vein.

### SYMPTOMATOLOGY

Symptoms, when present, are those of ureteral obstruction. The condition may be present throughout life bowever without

causing symptoms

Examination of most of the kidneys in adults showed hydroureter and in varying degrees, hydronephrosis and pyonephrosis. Stone formation was an occasional accompani

None of the 3 cases in infants showed of obstruction pres-

 Hydronephrosis may be: nder sure exerted by the vena ca

lying ureter, or by kinking or stricture due to the anomalous course of the duct. Uebelhoer states that in certain cases the constriction may be due to the right ovarian vein crossing the postcaval ureter

In our own case the symptomatology consisted of dull backache high up between the shoulder blades of 3 weeks duration accompanied by hematuris on two occasions severe headache at night and intermittent burning on unnation

#### DIAGNOSIS

In only 1 of the reported cases (Harrill s) was the diagnosis made preoperatively—a not extraordinary fact perhaps, when one considers the extreme ranty of the anomaly Cognizance on the part of the examiner that the condition may exist would appear to be a most important factor in preoperative diag nosis since the x ray findings are quite dis tinctive.

In Harrill a case the clinical picture was that of obstruction. Bilateral stereoscopic pyeloureterograms revealed a hydronephrotic right kidney with an elongated pelvis. From the preteropelvic junction the preter curved upward in a wide are toward the midline then downward toward the right side after which it continued downward in a normal course. As an important aid in diagnosis this author sug gests a complete series of stereoscopic roent genograms taken in the anterior posterior and oblique positions. He states "When viewed stereoscopically the radius of curva ture should be great enough to include a structure having the diameter and position of the vena cava

Another distinctive x ray finding that has been pointed out is the peculiar position that to the spinal column when the ureter Len In at roent lateral i, which of genograf found vens 4 courses i spine the ! tı t while away In t

bo yond the winding

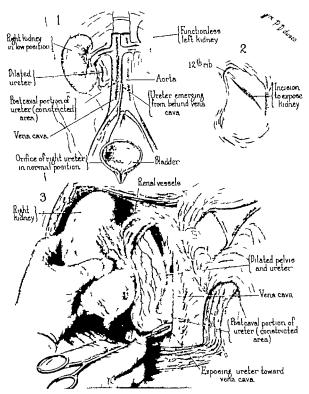

Fig 1 Condition before operation. Right kidney in low position ureter passes behind vena cave, and this portion of ureter is constricted. Left kidney is functionless. 2 Incision to expose right kidney and upper part of ureter 3 Kidney exposed Upper part of ureter and renal pelvis greatly dilated. Ureter being freed toward vena cave at point where it passes under the vein. Ureter constricted at this post (Indicated by dotted line)

shaped curve with the convexity directed supermedially The roentgenograms in our

the midline of the spinal column This patient had a left kidney shadow and a left ureteral case showed the right ureter to be very near orifice in the bladder but the ureter could not be catheterized nor was there any evidence of shadow casting material in this region in the intravenous urogram

In most of the reported cases in which operation was done the clinical picture was that of ureteral obstruction with the cause of the obstruction remaining obscure. It is our opinion that postcaval ureter should be considered in all cases of hydronephrosis of obscure citology, especially when the roentgenograms show a double right-angled kink with the ureter below this point displaced toward the middine.

### TREATMENT

Corrective surgery—namely transference of the ureter from its anomalous position behind the vena cava to a more nearly normal site—is the procedure of choice. In some cases however the kidney will be found so badly damaged that nephrectomy becomes necessary.

A review of the 11 cases in the literature in which operation was done discloses that ne-phrectomy was performed in 6 nephrolithot omy alone in 1 and corrective procedures in 4 (Kimbrough 1932 Ubelhoer 1936 May 1938 Harrill 1949) In all 4 cases the ureter was divided discussing from the retroperi toneal tissues drawn from behind the vena cava placed in normal position and anastomosed Harrills was the only case in which the division and anastomosis were above the ureteropelvic junction. The results in all 4 cases were reported as good

In our own case because it was deemed advisable to preserve the intrinsic nerve supply, the ureter was severed at its point of entry into the bladder wall removed from behind the vena cava and placed in normal position and its end reimplanted in the bladder wall as described below

The past history was unimportant. The right kidney could be left on palpation. Thurne showed 10 per cent pus and an occasional red blood cell, the prostatic secretion showed to per cent. pus otherwise the physical examination including

rectal examination was essentially negative A complete prological investigation was done Cystoscony revealed trabeculation in the region of the left ureteral orifice and considerable edema of the vesical orifice A lea I catheter to 6-I' pa sed to th Li lnes pelvis on the right side but a No 4 F cath eter could be passed only about a centimeters on the left side. The x ray films showed a small kidney shadow high in position, on the left side and a Lid ney shadow large in size and low in nos tion, on the right side. There was a large moth-eaten shadow opposite the transverse process of the third and fourth lumber vertebrae and another just opposite the fifth lumbar vertebra these were thought to be calcified Is mph glands. The right pyeloureterogram showed a greatly lilated kidney pel n and a right angled kink of the ureter None of the shadow casting material entered the left side. Excretory programs at c 10, and 25 minutes were made. These showed prompt function on the right ide and no evidence of function on the left The impression was that the patient had a dead

left kidner and a right hydronephrosis with a kink of the ureter

Two days after admission the right kidnes was exposed under spinal anesthesia

OPERATION

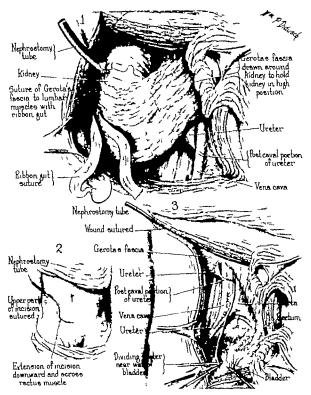

Fig. 3. 1. A nephrostomy tube has been placed in the kidney pelvas and fixed in position by ribbon gut. Nephropery is being carried out by drawing Gerota a fascia around the kidney and suturing it to the quadratus lumborum muscle with ribbon gut. 3, Upper portion of wound partity closed. Insign extended downward and across rectus muscle to expose middle and lower poetion of ureter. 3, Entire quere has been exposed. Dividing ureter close to its insertion in bladder.

The patient was then placed on his back and the lower end of the wound extended down the right border of the rectus muscle and

across its lower end to the midline. The in cision was deepened to but not into the peri toneum, which was bluntly dissected free and

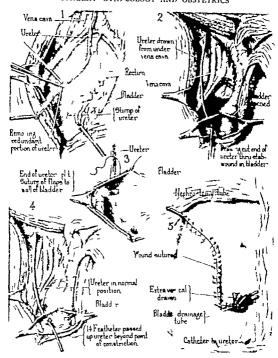

Fig. 3. Removing relundant position is directly a Uriter has been dea. I from under treas ears cut end being dea. through stats sound to bladder 4. the vena cava exposed. The ureter was identified to it under it, and passing down mesially across the left iliae vein just before it

joined the right flux to form the vena cava.

The entire lower end of the ureter was isolated and because it was thought advis-

Fig. 4. Pyelogram and pyeloureterogram after the injection of 25 cubic centimeters of skiodan.

able to preserve the intrinsic nerve supply of the ureter it was tied off at its insertion into the bladder wall. The ureter was then drawn from beneath the vena cava and brought over the vein the bladder was opened, and the ureter reimplanted into its superior posterior wall and fixed in position with a chromic cat gut No oo suture about 6 centimeters of the lower end of the ureter being excised to allow it to be straight, without tension

A No 14 F splinting soft rubber catheter was inserted into the ureter beyond its nar rowed point and brought out through the bladder incision and fixed to the skin of the lower end of the wound. A double suction tube was inserted into the bladder which was closed and the tube attached to the fascia in the lower angle of the wound. Four grams of sulfanilamide were distributed throughout the wound. A drain was inserted to the opening in the bladder and another drain to the anastromosis of the ureter and the bladder.

The wound was closed in layers and the patient returned to his room in good con dition

Postoperative course After the removal of the splinting catheter the nephrostomy wound continued to drain Attempts to insert a catheter by means of the cystoscope were un availing and 6 weeks after the first operation it was decided that the patient should again be operated upon

The bladder was exposed by a Pfannensteil incision extended upward on the right side It was opened and a No 10-F catheter was finally passed into the reimplanted ureter after incising the ureter about 3 centimeters above the bladder implantation at which point there was found to be a tight stricture The catheter was inserted into the Lidney pelvis and out through the urethra and fixed in position. The ureter was closed by a interrupted mattress sutures of No 2000 catgut The wound was closed in layers without a drainage tube in the bladder and the patient was returned to his room in good condition The No 10-F ureteral catheter thus passed from the Lidney pelvis through the bladder and the urethra

Subsequently a discharging sinus required still another operation at which time it was found that an abscess had developed about the lower end of the ureter and a considerable portion of the duct had sloughed off. The lower end of the ureter was, therefore implanted into the skin

The patient has made an uneventful re covery from this final operation The catheter

passes to a bag strapped to his leg and he goes about his work handling this apparatus vers well indeed

### 51 MM 121

1 Postcaval uniter is a very rare anomaly the present case being the thirty fourth to be reported in medical literature

2 This is an anomaly of the embryonic vascular system rather than the unnary being due to faulty development of the inferior vena cava. The productions vena cava is usu ally associated with other anomalies of the retroperatoreal vains

3. Of the 34 reported cases, 22 were dis covered at postmortem examination or laber atory dissection 11 (including ours) at opera tion and only a premeratively

4 I osteaval ureter may be present through out life without producing symptoms. Symptoms when present are those of ureteral obstruction which may be produced by pres sure exerted by the vena cava upon the under lying ureter or by kinking or stricture due to the anomalous course of the ureter

5 Stereo-copic roentgenogram taken in the antenor posterior and oblique positions aid in the diagnosis. The x ray appearances are distinctive in the following respects (1) In an oblique film the portion of the ureter dorsal to the vena cava will impinge against the lower lumbar spine whereas the normally situated uniter will fall away from it ( ) The postcavally placed uniter is always displaced toward to or even beyond the midline of the The ureter winding around the vessel forms a sickle-shaped curve with the convexity directed supermedially

6 Severe damage to the kidnes may re quire perhaectomy. Otherwise corrective surgery - namely tran ference of the ureter from behind the yena cava to its normal position in front of the vessel-is the treatment of choice

7 Only 4 cases treated by corrective sur gery have been reported previous to our own In 1 of these the ureter was divided and anastomo-ed in its upper portion in 1 the division and anastomosis were above the ureteropelvic lunction

8 The operation described here aims at the preservation of the ureter's intrinsic nerve supply while correcting the anomaly ureter is severed at its point of entry into the blackler wall removed from behind the vena cava placed in normal position and its end reimplanted into the bladder wall

### CONCLUSIONS

1 I ostcaval uniter should be considered in all cases of hydronephrosis of obscur, etiology particularly when the roentgenograms show a double right angled kink with the ureter be low this point di placed toward the midline

2 Divi ion of the ureter at its vesical end and reimplantation into the bladder wall is preferal le to divi ion and anastomosis higher up because (1) the peri taltic wave is not in terfered with and (2) stricture at the site of repair a less likely to occur

## TOPICAL PENICILLIN TREATMENT OF ESTABLISHED INFECTION IN COMPOUND FRACTURE WOUNDS

JOSEPH WEINBERG M.D., F.A.C.S. Major M.C., A.U.S. Van Nuys California

EPORTS concerning the use of parenteral and local penicillin ther any in the treatment of established suppurative infections in compound fracture wounds have been generally pessimistic. The poor results with parenteral therapy are explained by the failure of all but a small proportion of the administered peni cillin to permeate the edematous indurated zone of tissue which forms a wall about the site of infection. The principal advantage of local therapy is the high concentration of penicillin which is maintained at the site of infection. The chief objection to this method has been the difficulty of instilling the peni cillin solution at frequent enough intervals and with sufficiently sterile technique to obtain the maximum benefits. The purpose of this report is to describe a method of topical penicillin therapy which overcomes these difficulties and which has proved itself to be highly effective in a group of cases which had been refractory to previous treatment by other methods

The cases in which this method was used were of compound fracture wounds in which established infection had existed for periods ranging from 21/2 to 27 months before starting the method to be described in which peni cilin telly a mixture of penicilin with lubri cating jelly is applied to the surface of the wound For the most part, the wounds were produced by shrapnel machine gun fire and rifle fire with resulting extensive destruction of soft tissue and bone. All of these cases had been refractory or had shown little progress with previous treatment, and have shown a greatly increased rate of healing with the change to topical application of penicillin In some instances this response has been spectacular healing taking place within a few weeks in wounds which were resistant to other methods of treatment for a period of months.

The average time between wounding and the start of penicillin jelly treatment in the 28 patients comprising this series was 10 34 months The average time between the initiation of penicillin ielly therapy and complete healing in 23 of the 28 patients was 1 16 months. There were two failures with the penicillin jelly treatment in the sense that the soft tissue wounds failed to heal completely Three patients remain unhealed at the time of this report but their progress indicates that healing will be complete within a reason able period without changing the type of therapy These wounds had existed for an average period of 16 months prior to peni cillin jelly treatment, and showed satisfactory progress but incomplete healing after an average period of 4 months of this therapy 1

### RATIONALE OF TOPICAL PENICILLIN THERAPA

The pathologic process at work in old compound fracture wounds is a vicious circle in which localized infection of bone usually goes on to sequestration. The infected bone and the sequestra act as local sources for further infection of bone and surrounding soft tissues which in turn causes further degeneration and sequestration. The cycle will continue as long as sequestra are present or supportation persists.

The aim of the penicillin treatment is to break up the vicous circle by eliminating or minimizing the infection in the wound while awaiting sequestration and to arrest infection after sequestra are eliminated. The penicillin mixture to be described when retained in surface contact with the suppurating area in sufficiently high concentration acts as a strong deterrent to infection and when used in conjunction with adequate drainage elimination of sequestra, asoptic technique and general supportive measures has proved to be

 $^{10}\mathrm{Discryation}$  of these patients—as interrupted by the transfer of the author to another hospital.

Fig. Case 3 a, Appearance of thea, June 0.44. A large fragment of devitalized bone was left in the because of the possibility of its regeneration. b, Appearance of the tilha August 0, 0.45. far more effective in promoting bealing than has any other method previously used by us in this type of disease

### TECHNIQUE OF TOPICAL APPLICATION OF PENICILLIN

A matture of pentallin and lubricating jelly in the proportion of 1000 units per cubic centimeter is applied directly to the wound at each dressing the standard United States Army lubricating jelly containing phenylmercuric acetate 15000 glycerite of traga canth quince seed and aromatics being used. This vehicle which is water soluble releases penticillin more readily than would an ontment base and its consistency assures its contact with the wound for several days. The acidity of the lubricating felly which is in the vicinity of pH 4.4 apparently does not inhibit the action of the penicillin. The penimental proportion of leavest partial leads to the penicillin of the penicillin and the state of the penicillin in the penimental proportion of leavest partial leads to the penicillin and the state of the penicillin in the penicillin of the penicillin in the penicillin in the penimental penime

used alone in some of the earlier treatments and the results were less saturfactory. Lubricating jelly is in itself a bacteriostatic agent and probably enhances the value of penicillin. An opportunity to compare the effects of penicillin jelly and lubricating jelly without penicillin was afforded in a patient

cillin jelly is prepared by mixing i cubic centimeter of normal salme solution containing 20 000 units of penicillin with 19 cubic centimeters of autoclaved lubricating jelly as a sterile medicine glass. This mixture is prepared just before beginning the wound dressings and is usually sufficient for 6 to 8 dressings. The wound is cleaned with hydrogen peroxide followed by normal saline solution, immediately preceding the application of the penicillin jelly. Hydrogen peroxide appears to be a valuable adjunct in the treatment and there is no evidence that it lessens the effectiveness of the penicillin when it is used in this manner. Normal saline solution was sixed allowed across of the expellit when the used in

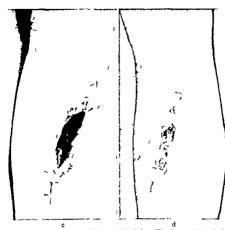

Fig. 1. c, Filling of wound defect by blood clot. The clot was injected with penicillin solution and was overlaid with penicillin july to prevent infection and thus encourage organization. d, Finel wound healing following split thickness kith graiting of the surface of the organized blood clot.

with wounds on the medial and lateral aspects of the leg Penicilin jelly was used on the severe medial wound and the standard lubricating jelly was used on the relatively minor lateral wound. After 2 weeks of treat ment the medial wound was completely healed while the lateral wound showed only moderate improvement. This and other observations offered convincing evidence that the beneficial effects of penicillin jelly are not due to lubricating jelly alone.

Dressings were made at intervals varying from daily to every fifth day during the experimental phase. In most instances there was evidence of bacterial growth if the dressing interval extended beyond the third day. The most favorable response was with dressings daily or every other day and since the wounds did just as well with dressings every other day that interval is now used routinely. The only exception is in the first few days of the treatment when suppuration is profuse. At that time it is well to apply the penicilium

mixture daily its efficacy being lessened by the mixture with pus. After several days often within 2 days the wound becomes so dry that the gauze dressing is found to be fixed firmly to the wound at each dressing. This adherence is due to the drying action of the lubricating jelly and to the lessened purulent secretion.

Strict surgical technique is observed in per forming the dressing. This is especially important in a large ward with a variety of septic wounds where cross-infection with organisms of high virulence is a constant danger. The dressers wear caps face masks and gowns the patient's mouth is away from the wound and the dressings are done in a private room whenever possible in order to avoid the dust of the ward. Casts are changed if they become soiled with exudate. Instrument technique is used throughout.

Treatment with penicillin jelly has distinct advantages over the method of instillation of penicillin solution through tubes The latter

This and other observations offered convincing evidence that the beneficial effects of penicillin jelly are not due to lubricating jelly alone.

Dressings were made at intervals varying from daily to every fifth day during the experimental phase. In most instances there was evidence of bacterial growth if the dressing interval extended beyond the third day. The most favorable response was with dressings daily or every other day and since the wounds did just as well with dressings every other day that interval is now used routinely. The only exception is in the first few days of the treatment when suppuration is profuse. At that time it is well to apply the penicillin.

mixture daily its efficacy being lessened by the mixture with pus. After several days often within 2 days the wound becomes so dry that the gauze dressing is found to be fixed firmly to the wound at each dressing. This adherence is due to the drying action of the lubricating jelly and to the lessened purulent secretion.

Strict surgical technique is observed in per forming the dressing. This is especially important in a large ward with a variety of septic wounds where cross-infection with organisms of high virulence is a constant danger. The dressers wear caps face masks and gowns the patient's mouth is away from the wound and the dressings are done in a private room whenever possible in order to avoid the dust of the ward. Casts are changed if they become soiled with exudate. Instrument technique is used throughout.

Treatment with penicillin jelly has distinct advantages over the method of instillation of penicillin solution through tubes. The latter

 $\Gamma$ g 2. Case 30. a, Perforating wound of lower third of femur with dependion due to loss of soft tissue and bone. b, Appearance of soft tissue wound 20 months after wounding. Exposed bone 1 partially covered with suppurall g

granulation treare c. Treatment of the ound ith penicillin jelly for 27 days followed by split thickness skin grafting of exposed bose surface has resulted in complete healing

method was used in earlier cases, but was discontinued because of the difficulties en countered in administering the treatment. The chief objection was that the instillations were often made by unskilled personnel and it was unpossible to prevent micro-organisms from entering the wounds through the tubes due to errors in handling syringes and in managing the ends of the tubes. Three of ro wounds thus treated became contaminated with bacillus pyocy aneus within a period of 2 days. Another objection was the work en tailed in making the instillations at intervals of 3 hours in a large number of cases.

### BACTERIOLOGY

Bacteriological studies were made to determine the organisms present in the wounds and to determine the resistance of the infecting bactera to various concentrations of peni cultum. The finding of especial interest was the tendency of organisms which persisted in the wounds to show a progressively increasing resistance to the action of penicillin. This was particularly noticeable with Bacillus proteus. With the beginning of treatment several

wounds showed cultures of Bacillus proteus which were completely inhibited by concentrations of penicillin as low as 25 units per cubic centimeter. Cultures taken after 2 weeks showed Bacillus proteus from the same wounds to be completely resistant to concentrations of 1000 units per cubic centimeter For the most part Bacillus proteus was resistant from the beginning to concen trations of 250 units per cubic centimeter or higher This was also the case with Bacillus pyocyaneus Staphylococcus was susceptible to low concentrations of penicillin in most instances Twelve cultures showed complete inhibition with 25 units or less 1 was suscept ible to 100 units and 1 to 250 units There was little opportunity to check variations of susceptibility in this organism during penicillin therapy as the staphylococcus usually disappeared after a few days of treatment Organisms which showed complete resistance to concentrations of 1000 units of penicillin per cubic centimeter including Bacillus proteus and Bacillus pyocyaneus, did not prove to be troublesome contaminants, and usually disappeared from the wounds within a few

weeks. There has been an unusually high incidence of Bacillus proteus in this group of patients. This may be explained by the fact that a majority were previously treated with penicillin intramuscularly or with sulfona mides and the resistant proteus bacillus re mained in the wounds after other organisms had been made to disappear

Suppuration has been controlled in all of the wounds treated by this method regardless of types of bacteria present so it is not considered essential to make detailed bacteriological studies except for investigation purposes

### CLINICAL AND PATHOLOGICAL FEATURES OF WOUNDS TREATED

The 28 cases of compound fractures with long standing wound infection which comprise this series had been refractory or were slow in response to treatment by other methods before beginning the treatment with penicillin jelly Wounds of short duration and wounds which were near completion of healing when the penicillin jelly treatment was started are not included in this report. The injuries treated involved the following bones

Tibia, or tibia and fibula
Tarsal and metatarsal bones
Femur including hip joint
Shoulder joint, involving head of humerus
Shaft of humerus
Sacrum, complicated by pelvic abacess

The local pathologic changes which were considered most significant in influencing the course of the disease were suppurative cellulitis, edema of varying degree localized degeneration and necrosis of bone with or without sequestration degeneration and ne crosis of the soft tissues and impairment of regional circulation due to direct injury edema thrombosis and trophic changes. In addition there are to be considered the variables of the injuring force and the depth and irregularity of the wounds. As stated previously the types of bacteria did not appear appreciably to influence the course of the healing

### INFLUENCE OF BONE SEQUESTRATION ON

The course of wound healing was influenced as much by the proper removal of sequestra as

Fig. 3. Case 21 a, left, Appearance of femur 7 months after refracture. An intractable draining wound persisted throughout this period and was thought to be responsible for lack of tendency to union. b Secondary closure following 31 days of penicilian jelly treatment resulted in permanent bealing of the soft thisse wound and union of the fractured femur

by any other factor Removal of large sequestrated fragments was delayed as long as there appeared to remain a possibility of revascularization. This has caused a delay in healing in some cases because of the eventual complete necrosis of the fragment but the value of the segment if it did revascularize more than compensated for the delay in healing time. The following case illustrates this point

Case 22 Revascularization of devitalized bone segment (Fig. 1)

Patient, aged 30 years, was wounded in combat by shrapnel early in February 1944 sustaining a severe

Fig. 4. Case 3% a, left, Perforating fracture of sacram with builet lodged in pelvis. Multiple operations for drainage over period of 3 months, and removal of the builet were unsaccessful in resting suppursalive infection i pelva b, I jection of smus tract, originating in the pelvia and emerging over the left greater trochaster

with contrast sections also the principal pocket in the left liker region within the perist. The abscess, which had persisted for so months, because healed after 4 days of treatment with periodizin jelly indeed in the tract every other day. Observation for 6 months following healing also an evidence of recurrence of infection.

compound comminated fracture of the middle third of the tibis. Early treatment included débridement sulfadiazine orally and closed cast which was continued until June 12 1041, at which time it was decided not to remove a large deviablated segment of cortical bone because of the certainty of weakening the tibis by its removal

The would was then treated for several months with various topical medications including sulfathla zole outtiment anothloramide solution and aquirous solution of penicillin in the strength of roco unit per cubic centimeter. The would remained indokent with luttle roentgeoological evidence of bone regeneration in the devitatized segment of tibas.

Penicillin jells treatment was instituted December 11 1944 following which there was prompt epithelization if the wound together with evidence of progressive regeneration in the devitalized bone and

union of the fracture.

Small spleuhes of sequestrated bone became de tached from the regenerating cortical fragment from time to time and operation was performed on March 14, 1945 for removal of devitalized bone from the surface of the fragment. The wound defect was allowed to fill with blood. It was not possible to close the soft tissues over the defect. The blood clot which formed was treated with injections of several drops of penicillin. In normal saline solution coo units per cubic centimeter on the first third and fifth days following operation. Intramuscular injections of penicillin, 20 coo units every 3 hours were given for a period of 15 days beginning 2 days before operation. The blood clot was covered with

penicillin jelly

The clot became organized in 3 weeks and was
then covered with split thickness skin grafts. Sur

face healing was complete on April 30 1945 Later x ray examinations showed satisfact ry union of the revascularized segment with the shaft of the tibia.

The importance of carefully planning the operation of sequestrectomy cannot be over emphasized The sequestrum should be accurately localized beforehand by roent genographic study with views in addition to the standard anteroposterior and lateral whenever necessary. The incision is planned to permit a direct approach to the necrosed bone with a minimum of disturbance to living bone and soft tissues. In some of our patients it was necessary to make the incision through normal skin away from the wound to ac complish this. In 2 instances in this series, wound healing was unnecessarily delayed because of failure to remove all of the sequestra present. In these cases the operative incisions were madequate for proper exposure of the diseased area.

All operations of sequestrectomy as well as other types of revision operations are preceded and followed by several days of intra muscular penicillin therapy

The particular advantage of topical treat ment with penicillin jelly in wounds harboring sequestra is that further necrosis of soft tissue and bone is held in check by the inhibiting effect of the penicillin on the infection thus breaking the vicious circle described previously

### PRESENCE OF DEGENERATED BONE

The difficulties of management of degenerated bone are much the same as with sequestra. Degenerated bone causes greater delay than does sequestrated bone because it is impossible in most instances to determine whether the degenerated bone will revascu larize or will go on to necrosis. Extensive loss of bone makes it necessary to conserve as much osseous tissue as possible therefore one must guard against sacrificing bone in which there remains any possibility of revasculariza tion The point is stressed that, although early healing is desirable, it is not so important that it should be attained through the sacrifice of valuable fragments

### EXCAVATED WOUNDS

Depressed wounds due to loss of bone substance especially those in which bone remains exposed, are definitely a cause of delayed healing. This is noteworthy in shoulder wounds with partial or complete loss of the head of the humerus in which the wound is held open by the surrounding bony promi nences Two such cases in which healing was making little progress with sulfathlazole ointment, azochloramide instillations and penicillin instillations used successively showed a remarkably rapid response to penicillin felly

CASE 25 Healing of shoulder defect

Patient aged 20 years was wounded in action on June 24 1944 sustaining a mortar shell injury with a severe compound fracture-dislocation of the head and neck of the left humerus, together with other

The wound was débrided and an Orr dressing in shoulder spice cast was applied. He was evacuated to the United States after several months arriving at this hospital September 5 1944 Removal of the cast several days after his arrival here revealed a deep cone shaped wound on the prominence of the shoulder measuring 5 centimeters in diameter and 6 centimeters in depth.

Closed cast treatment was continued until October 18 1044 after which time the wound was dressed through a fenestration with hydrogen per oxide cleansing and 5 per cent sulfathiazole oint ment. Healing progressed slowly and on November 16 the local therapy was changed to instillations of aqueous solution of penicillin 500 units per cubic centimeter through a small caliber soft rubber tube every a hours. Some improvement was noted with this change in treatment, but the method was cumbersome and there was evidence of wound contamination apparently due to faulty technique in mak ing the instillations.

Penicillin jelly treatment was started December 11 1944. Improvement was noticed within a few days and the wound which had remained almost stationary at 2 centimeters in diameter and 3 centimeters in depth for some weeks previous to the use

of penicillin jelly now healed rapidly and was com-pletely closed on January 30, 1945 Arthrodesis of the shoulder was performed on April 12 1045 with primary healing of the surgical

wound.

Healing by organization of blood clot was accomplished in 4 cases of tibial defect. Blood was permitted to fill the defect follow ing sequestrectomy and saucerization of the bone The resulting blood clot was injected with a few drops of a solution of 1000 units of penicillin per cubic centimeter of normal saline solution. The surface of the clot was protected by a dressing of penicillin felly Wounds treated in this manner showed gross evidence of organization of the blood clot 3 to 4 weeks after operation. In 2 instances, the organizing clot was overlaid with split thick ness akin grafts 4 weeks after operation None of the clots liquefied or became in fected, and there was only slight depression of the area on completion of healing. In the light of previous experience with organization of exposed blood clot it is reasonable to assume that penicillin played an important role in the healing in these cases (Fig. 1, c and

CASE 14 Healing by organization of blood clot. Patient, aged 27 years was injured by shrapnel in combat with the enemy October 26 1944 sus-taining a severe compound comminuted fracture of the upper portion of the left tible.

The wound was débrided within a few hours and was treated with sulfathiazole powder vaseline gause and a circular cast from the toes to the upper thigh.

The dressing was not removed until he reached this hospital January 8 1945 at which time there was evidence of moderate suppuration with frag mentation of the tibia.

Operation of sequestrectomy and ostectomy was performed January to at which time several long splinters of necrosed bone were removed. Culture of the wound revealed Bacillus proteus which on

trating was inhibited by aso units of penicilia per cubic centimeter. A large defect in the tibia and soft tissues so centimeters in length 35 centimeters in width and 5 centimeters in depth was allowed to fill in with blood clot. Several drops of penicilini in normal saline solution, 1000 units per cubic centimeter, were injected into the blood clot on the first and third postoperative days. The surface of the clot was overlaid with a thic costing of peniciliin jelly. The clot organized with moderate retraction, and was covered with split thickness skin grafts on February 7. All grafts were successful, and bealing of the wound was complete on March 1 1016.

### EXTENSIVE LOSS OF SOFT TISSUE WITH EXPOSURE OF BOVE

Exposed bone is a deterrent to wound heal ing because of its tendency to degeneration and necrosis as long as it remains uncovered even though infection is held in check. Therefore an effort is made to cover the exposed bone with soft tissue at the earliest favorable time. Good results have been obtained by placing split thickness skin grafts directly on bone after gross evidence of necrosis and infection has disappeared even though wound cultures remain positive. The skin-grafted surface is treated with compression dressings moistened every other day with normal saline solution containing 1000 units of penicillin per cubic centimeter and compression is main tained for a period of 8 to 10 days This procedure was used in 5 cases in which an infected open wound had been present for from 6 to 28 months. All except a healed completely. The single case of failure was a tibial compound fracture wound which had remained open with bone exposed for 20 months following metal plating. There was no gross evidence of bone necrosus or suppurative infection follow ing operation of skin grafting and it is probable that failure was due to inadequate circulation in the exposed bone

Cast 20. Skin graiting of exposed bone surface following treatment with penicillin jelly (Fig. 2)

Patient, aged 21 years, was injured by shrapnel in overseas combat April o 1913 receiving a perfor ating wound of the distal third of the femur with loss of the patella.

Treatment prior to his arrival at this hospital April 8 1944, consisted chiefly of blood translusions and plasma infusions penkellin intramuscularly closed cast treatment, and two operations f sequestrectomy Examination here disclosed a large open wound on the anterior of the lower third of the thin with an irregular periorating wound of the femor. The wound was treated with sulfathlazole ointment dressings until October 17 at which time the bone was saucerized to encourage overgrowth of soft tissue.

Topical penicilin in normal saline solution every a hours was started Aovember 6 1944. Cultures at this time showed the presence of nonhemolytic Staphylococcus albus and Hacillus protess. The profuse supportuse supportus supports supports of the start of the start

bone was negligible
Pendillin Felly treatment was started December
15 1041 and the supportation subsided completely
within 10 days. Split thickness skin grains were appilled over an area of exposed bone 5 centimeters in
length and 2 centimeters in width on January 11
1945. All of the grafts remained viable and the
wound was completely heated on January 23 1915

Secondary wound closure by suturing was usually not possible because of the loss of the loss of tissues. Only 2 cases in the series were suit tissues. Only 2 cases in the series were suit able for this procedure. One of these described in the following case history illustrates the favorable effect of the procedure on a fractured femur which had shown little tendency to unite before the wound was closed secondarily

Case at Secondary would closure by suturing

(Fig. 3)
Patient, aged 21 years, received a bullet wound
November 21, 1043 which caused a fracture of the
middle third of the left femur. He was treated in
traction, followed by hip spics cast until May 30,

He refractured the femur June 17 1944 while out of cast, and was admitted to this bospital I month later Examination here disclosed a comminuted simple fracture of the middle third. The extremity was put in traction. An abscess formed in the soft theres in the region of the fracture and this was drained August so 1944. Ills condition, which had been critical, improved rapidly following adequate drainage. However drainage continued unabated. A large femoral fragment showed evidence of ad vanced degeneration and showed little tendency to unite to the proximal and distal main fragments. The soft tissue wound was intractable to treatment with sulfathiasole cintment, and showed little response to instillations of asochloramide solution and penicillin solution used successively

Penicillin jelly treatment was started December 13 1914, and was continued until January 12 1934 that time the trough-shaped wound, measuring 15 centimeters in length and 5 centimeters in depth abowed no suppuration, and was epithelialized ex

cept in its depth Secondary closure of the wound was performed January 12 1945. The wound re mains completely healed after a period of 4 months and the femur above evidence of increase in callus formation with amparent union.

### INACCESSIBLE WOUNDS WITH SINUS TRACTS

There have been several cases of deep sinus tracts in which it was inadvisable to explore the depth of the wound by surgical operation These patients were examined roentgenolog ically following injection of a radiopaque medrum into the tracts through a soft rubber catheter after making certain that there was free exit for any substance injected Follow ing this examination to determine the extent of the pockets of infection penicillin jelly was injected into the sinus tracts every other day The ment of the use of penicillin jelly in these cases hes in the fact that it is apparently harmless when it is retained in the wound One of the patients treated in this manner a pelvic abscess secondary to a bullet wound through the sacrum is of especial interest.

CASE 28 Healing of inaccessible wound with

sinus tract (Fig 4)

WEINBERG

Patient aged 24 years received an accidental 45 caliber bullet wound on June 12, 1943 the bullet entering the left gluteal region, piercing the middle third of the sacrum tearing segments of small bowel and sigmoid, and lodging in the pelvis. The intestine was repaired 2 bours later.

A large subpuble abscess was drained June 25, 1943 and a left retroperitoneal abscess was drained

August 12 1043

Ä flexion deformity developed gradually in the left hip and the hip became ankylosed with destructive changes in the joint cartilage. The earlier distinge of the pelvic abscesses had resulted in a persistent sunus emerging in the left lower anterior abdominal wall. In November 1943 x ray of the tract, with solused oils as a contrast medium, abowed ramifica tions extending toward the crest of the left filtum, the hip joint, and the ischium.

A total of 20,300,000 units of penicillin was given intramuscularly from February to August, 1944 Cultures of hemolytic streptococcus from the tract

were reported during this period

Exploratory surgical inculon was made in the left hip region over the greater trochanter on March 22 1944. There was no pus found in the hip Joint. An abscess broke through the exploratory hip incision on April 5, 1944. A subsequent pelvic operation per formed July 26 1944 was unsuccessful in arresting the drainage from the suns in the left hip region

The patient was transferred to this hospital September 10, 1044. At that time all surface wounds

were closed except the sinus tract emerging at the left hip Wound culture showed nonhemolytic Staphylococcus albus, nonhemolytic streptococcus, and Badllus proteus. The bullet was removed from the pelvis November 30 1944. There was no change in the drainage of pus from the sinus tract of the hip following this surgical procedure. No pus was seen in the vicanity of the bullet at the time of its removal.

Yray examination following injection of the sinus tract with radiopaque medium showed essentially the same findings as those previously described with the exception that the abscess in the

lower left pelvis was more clearly defined

Injections of pencillin felly into the ansus tract were started January 16 1945. The injections were made every other day through a No 12 soft rubber catheter 2 cubic centimeters of the felly being in stilled with very moderate pressure. The tract be came completely closed on January 30 1945, for the first time since the development of the sinus on March 22 1944, and has now remained closed for a period of 6 months. The white blood cell count and temperature remain normal and the patient is completely well except for an almost complete ankylosis of the left hip point.

It is possible that removal of the bullet played a part in the healing in this case but the fact that no communication was demon strated between the bullet and the abscess at the time of operation and the fact that the purulent drainage which had continued for 6 weeks following operation ceased promptly after penicillin jelly instillations would argue for penicillin jelly being the major factor

### INFLUENCE OF GENERAL DISTURBANCES ON WOUND HEALING

General factors which should be given consideration are the state of body nutrition the character and volume of blood, protein sufficiency vitamin balance, and concurrent diseases. It is difficult or impossible to measure the degree of departure from normal with ord mary methods in most of these factors except when the departure from normal is extreme Nevertheless it must be accepted that such disturbances do exist in chronic suppurative infections and that they should be considered as factors in influencing healing.

Protein insufficiency is a constant accompaniment of prolonged severe suppuration and a high protein diet is important in helping to overcome this deficiency. This is especially important for the solder returned from a distant outpost where some essential foods are

lacking and certain types of malnutrition are prevalent. Edema of the tissues in and around the wounds is interpreted as serious protein deficiency if circulatory cause can be ruled out. It has not been considered necessary to meas ure the proteins of the blood or to determine the albumin-globulin relationship except in patients with pronounced edema.

Vitamins which are known to be of import ance in wound healing particularly vitamin. C have been found to be low in most of the cases in this series. The need for this vitamin and vitamin B complex in greater quantities in those suffering from suppurative disease or in those who are undergoing wound healing has been satisfactorily demonstrated by research workers. The diet is supplemented with liberal amounts of orange juice and in addition to this a supplement of vitamin C is given intramuscularly if the patient abows a low vitamin C blood level These include patients abowing less than 0.8 milligram per 100 cubic centimeters of blood

A continued low blood level that does not improve with transfusions and adequate diet is usually due to suppuration. In such cases attempt is made to control infection by removal of sequestra or improvement of drainage.

Optimum circulation in the injured part is maintained by proper elevation by application of warmth in cases of vascular injury and by bandaging and splinting in such a manner as to prevent unequal pressure with its consequent accumulation of venous blood in the region of the injury. In this connection the principles of supportive and compressive band aging used in the treatment of vancose ulcers applies equally well to established compound fracture wounds of the leg

Local and general physical conditioning of the patient is continued throughout the treat ment except during penods immediately fol lowing major operations of sequestrectomy drannage, or wound revision Exercises are directed toward the conditioning of muscles in the affected extremity and muscles in general. This phase of therapy is especially important in patients whose wounds require months for healing BUMMARY

1 A method of topical application of pencillin in lubricating jelly in the treatment of established infection in compound fracture wounds is described. It has the advantage of maintaining high concentrations of penicillin in the area of the wound without the use of cumbersome technique or apparatus.

2 Evidence is presented of the effectiveness of this preparation in permeating the barriers in the zone of infection. This is in contrast to parenteral administration in which relatively small amounts of penicillin reach the area of

suppuration

- 3 Twenty-eight compound fracture wounds with established infection have been treated by this method. They had been refractory or slow in response to accepted methods of ther apy for penods varying from z to z 7 months, and all except z have shown a highly satisfactory response to treatment with penicillin jelly
- 4. Delay in the healing of old infected compound fracture wounds is most frequently due to the presence of necrosed bone. The presence of devitalized bone sets up a vicious cardin turn causes further necrosis of bone. Peni cillin jelly has proved itself to be effective in breaking up the vicious circle by eliminating or minimizing infection even in the presence of necrosed bone, and by inhibiting the soft tissue and bone infection after the sequestra are removed.
- 5 Skin grafting secondary wound closure and healing by organization of blood dot have been successful in most instances in the patents in this series treated with penicillinjelly. From the author's experience and the experience of others, such procedures would seem to have been less successful without its use.
- 6 Topical penicillin therapy is to be considered as a part of a general plan of treat ment. Good surgical judgment proper surgical technique maintenance of an optimizer of the proper surgical technique maintenance of a proper state of nutrition are absolute essentials in the treatment.

# IS THE BIOPSY OF NEOPLASMS DANGEROUS?

## An Experimental Study

# MARK E. MAUN M D., and W F DUNNING Ph.D., Detroit, Michigan

LINICIANS are prone to avoid the incision or removal of neoplasms for fear that the diagnostic procedures may serve to dissemunate tumor cells but the reluctance to obtain a biopsy specimen for histologic study often delays adequate therapy and invalidates an accurate diagnosis. It is generally accepted as a truth-and there is some experimental evidence to support the belief-that the rupture of the capsule of a tumor or the destruction of adjacent tissue structures incurred in obtaining a biopsy spec imen may serve to open vascular and lym phatic channels to tumor cells Physicians therefore avoid manipulation of suspected tumors in order to prevent local extension or metastases. These concepts imply that the extent of neoplasms can be roughly judged by gross inspection and that tumor metastases are usually limited by the observed tissue

Clinical evidence supports the theory that any degree of trauma either accidental or sur gically intended may serve to disseminate a malignant tumor and in rare instances to alter the nature of a benign growth. Thus students are cautioned by their elders not to squeeze or unnecessarily disturb a tumor in deed at times only a single student of an eager class is favored with an opportunity to touch gingerly the restrained new growth medical novitiates learn to regard any new lump fearfully as though its mysterious walls might disintegrate if the tumor cells were disturbed This acquired fear of tumor dissemina tion is readily increased as the physician may unjustly attribute rapid and abundant em bolic phenomena to his operative intervention in a seemingly localized new growth.

If one should accept the aforementioned theses that a tumor growth is completely lo-

calized by its capsule, by adjacent tissue bar ners or by unyielding vascular channels then interruption of such defenses might lead to a sudden catastrophe with rapid invasion of local and distant parts However a critical study of surgical and postmortem specimens gives ample evidence that neoplasms are not restrained or unduly inhibited by their capsules or areas of marked desmoplasia since metastases may precede capsule formation and emboli may readily flow in lymphatic channels found in encircling tissue barriers There is also adequate evidence to suggest that tumor emboli may occur throughout the life of a tumor and that growth in distal parts depends on the adaptability of the invaded tissues to the repeated attacks of viable em boli. It would not be unreasonable therefore to think that inoculation of an organ with a large mass of tumor cells might well produce a viable metastatic focus while an embolus of only a few cells might succumb to tissue de fenses Hence a decrease in the bulk of a neoplasm available for metastases should serve to decrease the incidence of metastatic tumor growth The most likely danger therefore from cutting into a tumor would be the me chanical transfer of neoplastic cells to the operative incision follows careful operative procedures This accident seldom

If one examines the medical literature rela tive to the danger of biopsy procedures it is obvious that the experimental evidence is con tradictory and inconclusive. It is therefore not surprising that clinicians are in a quandary when confronted by a suspected malignancy The value and the dangers of biops; were stressed in the medical literature in 1917 (3) when it was proposed to submit biopsy speci mens to the Health Department of New York City In the heat of the controversy editornals and numerous articles written by clinicians vigorously condemned the practice of obtain ing such specimens. Well known surgeons of

From the Department of Pathology, W. 3 ne University College of Medicine, in co-operation with the Detroit Insultor of Cancer.

that day referred to a biopsy as a criminal act, since fincision into a breast tumor renders the prognosis grave or hopeless. The late Dr Ewing however was of the opinion that a clean surgical incision produced no untoward results and pointed out that the diagnosis was often impossible without histologic study Tyzzer in 1013 demonstrated that daily massage increased the number of metastases in experimentally produced tumors in animals. F C Wood in 1919 injected rats with amall pieces of a carcinoma and after several weeks excised parts of the tumor in one group and the entire tumor in a second group Animals of a third group were used as controls. The animals were sacrificed in 3 to 4 weeks. The percentage of metastases in the third group that in which biopsy specimens were not obtained was 32 while in the first group the per centage of metastases was 22 In the group in which the tumors were completely excised the percentage was 21.8 In 1922 knox in the same laboratory inoculated mice with a transplantable tumor and massaged the resulting growths daily These inoculated ani mals and the animals of a control group were sacrificed 4 weeks following inoculation was apparent from this experiment that massage promoted metastases. Marsh working with spontaneous tumors in mice found that massaging these breast tumors increased the percentage of pulmonary metastases.

In a carefully controlled clinical study, Peterson and Nuttall selected two groups of squamous cell carennomas of which the size treatment, and course could be readily observed. From one group a buppsy specumen was removed with no attempt to control the degree of trauma. In the control group diag nosis was made upon clinical inspection. Both groups of tumors were treated in a similar manner and followed for a period of 2 years. At the end of this period the 166 cases in the two groups were reviewed and it was found that the incidence of metastases had not been

increased by the bloosy procedure.

After reviewing the avallable experimental evidence. Peyton was of the belief that the harmful effects of trauma had not been completely proved. He had the clinical impression that infiltration of a tumor with local anes-

thems could disseminate a neoplasm. He injected mice with various tumors. In one group the tumors were subsequently removed under general anesthesia while in another group local anesthesia was applied about the tumor. In the latter group in which metatases were usually infrequent, pulmonary nodules were abundant following the injection of the local anesthesia. He concluded that the use of local anesthesia for the removal of a neoplasm might be a dangerous procedure

Since present medical opinion and experimental evidence are not entirely in accord it seemed desirable to investigate the problem further employing more biologically uniform material. With the development of relatively homogenous inbred stocks of rats and mice and a diversity of carcinogenic agents, the experimenter has at his command a limitless array of transplantable tumors with 100 per cent predictability of progressive growth. By the transplantation of small fragments from an induced or apontaneous tumor into any organ or tusue of other hosts of like genetic constitution the experimenter may duplicate many thousands of times, if desired, the growth of the same neoplesm. The difference between these transplanted tumors and the same tumor in the primary host is that the causative agent is not operative in the sec ondary hosts. However such material is ideally adapted to the study of the effects of any procedure on tumor growth

### MATERIAL AND METHODS

The transplanted tumors used in the present experiment arose spontaneously or were induced in relatively homogenous inbred rats and were transplanted into hosts of the same inbred line. All were progressively growing neoplasms which had been propagated by transplantation from 6 to 150 generations previously.

For the first experiment IRS 4317 a very malignant Cystocrus-induced fibrosarcoms was selected. The history on transplantation of this tumor has been previously described by Dunning Curtis, and Bullock (1). The rats were inoculated on the right forefoot with 2 milligram grafts of a tumor from the 150th transplanted generation. Nine days after in-

0.5 centimeter in diameter they were completely excised No attempt was made to remove a margin of healthy uninvolved tissue. The skin was secured with one or two inter ruptured sutures.

The tumor used in the second experiment was R 2426 a spontaneous papillary cystad enocarcinoma of the mammary gland study of the growth of this tumor on transplantation has been reported by Eisen. Frag ments weighing approximately 3 milligrams of a tumor from the 31st generation were in serted under the skin of the right side by means of a trochar This tumor grows rela tively slowly and the biopsy was not per formed until 60 days after inoculation when the tumors weighed approximately 5 grams An incision about 1 centimeter in length was made with a knife through the akin and a wedge shaped slice of tissue about 02 cents meter at the margin was removed. Since the tumors were somewhat cystic and hemor rhagic a considerable amount of bloody fluid and tissue exuded through the incision when experiments the capsule was cut. When the hemorrhage subsided the wound was cleansed and closed

Rats bearing transplanted adenocarcinoma of the 10th generation of R2572 were used for the third experiment. The primary tumor was a mixed tumor of the mammary gland The separation of the epithelial portion has re

cently been described by the authors (2) The tumors were unplanted similarly to R2426 and 22 days after transplantation when they weighed approximately 5 grams a simple bi opsy was performed. This tumor is fairly firm in consistence and only a small mass of tissue was removed and the wound closed with a suture.

For the fourth experiment rats bearing transplanted squamous cell carcinoma M-C osi were used The primary tumor was

induced by a 3 milligram pellet of methylcholanthrene in the prostate gland of an agouti Irish male rat of the 24th BxS genera tion of AxC line 9935 and has not been pre viously reported. Transplanted tumors of the 7th generation were used for this experiment and the biopsies were performed 20 days after implantation when the tumors weighed approximately 5 grams as in the two previous

Following the biopsy the tumors were al lowed to grow until death of the rat occurred. A careful postmortem examination of the bi opsied and control series included measurement and weight of the neoplasm and exammation of the superficial lymph nodes lungs and skeleton for metastases. The lungs were injected with 10 per cent formalin and pre served with a section of the tumor and the lymph nodes for microscopic examination

All preserved tissues were examined thor oughly The biopsied series were compared with the control series for the average number of days which they survived after transplantation and for the percentage with metastases.

### RESULTS

The results are summarized in Table I. In the first experiment 19 rats of the control series bearing fibrosarcomas survived an average of 28 days after inoculation. The tumor removed postmortem weighed an average of 21 grams 15 or 79 per cent, of the rate had lymph node metastases and 17 or 90 per cent, were found to have lung metastases. In the experimental series the 19 rats which had their tumors excised o days after inoculation sur vived an average of 42 days. The difference in average survival period of 14±3.8 days is statistically significant and represents the equivalent of nearly a year and a half in a man a life. The average weight of the tumors was 34 grams and larger than the tumors of the control series but the percentage of lung and lymph node metastases was not increased being respectively 84 and 63 per cent.

In the second experiment 19 rats of the control series bearing adenocarcinoma R 2426

survived an average of 98 days. The tumors weighed an average of 24 grams and only 5 or 26 per cent, had lung metastases. One, or 5 per cent, had axillary lymph node metastases. The 20 rats in the experimental series survived an average of 125 days. The average tumor weight was 15 grams. Three or 15 per cent, had axillary lymph node metastases and 12 or 60 per cent, had lung metastases. The difference in average survival period of 27 ± 8 s days in favor of the rats operated upon is also statistically significant and represents the equivalent of nearly 3 years in a man s life. The tumors were smaller than in the control series averaging only 15 grams. The differ ence in average weight of the tumors in this series was probably due to more extensive ulceration and the prolongation of average survival time was a result of the removal of a considerable mass of the tumor in the opera tive procedure. The significant increase in percentage of lung metastases was a result of the increased survival period Figure 1 shows the length of survival of each rat in the two series, with the individuals which showed microscopic and gross lung metastases desig nated by cross-hatched and blackened bars respectively. In the control series 3 rats in which lung metastases were discovered by microscopic examination survived 80 96 and 100 days. Three rats in which no lung involvement was detected survived 101 108 and 177 days and the 2 rats with extensive gross metastases survived for 164 and 165 days. Among the rats operated upon microscopic lung metastases were observed in 3 rats which survived respectively 80 80 and 95 days. Three rats died after 106 110 and 247 days respectively with no lung involvement and all but 2 which died after 106 and 117 days, respectively of those with gross lung metastases survived any of the control series which died without lung involvement.

In the third experiment 20 rats of the con-

trol series bearing  $\frac{R_{-2572}}{10 \text{ A}}$  survived an average

of 110 days after transplantation. The tu more weighed an average of 61 grams and only 3 or 20 per cent, had lung involvement. In the experimental series 18 rats with biopsied tumors survived an average of 113 days with tumors which averaged 39 grams and 4 or 22 per cent, had lung involvement. There were 2 additional rats in this series in which the tumors practically ulcerated out following the operation. These two hosts survived for 276 and 373 days respectively Both had large tumors at necropsy. One had lung and lymph node involvement and the record on the other was lost. In this experiment employing a tumor of firm consistence in which the blopsy specimen comprised only a small fraction of the mass of the growth, no prolongation of survival period was noted and no difference in the percentage of metastases was detected except in the 2 instances noted in which secondary infection following the oper ation inhibited the growth of the tumor

In the fourth experiment 34 rats of the control series bearing M-C 951 survived an

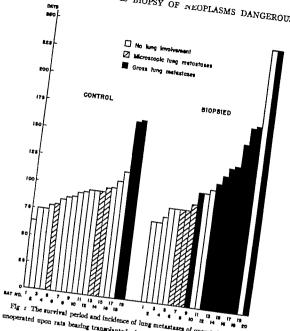

Fig. 1 The survival period and incidence of lung metastases of operated upon and unoperated upon rate bearing transplanted adenocarcinoma  $\frac{R}{2400}$ 

average of 93 days and the 20 rats of the ex perimental series in which the tumors were biopsied 20 days after inoculation survived an average of 95 days. Since these tumors char acteristically ulcerate early the tumor weight in both series was based on the combined weight of the superficial lymph node metastases. In the control series the lymph node metastases averaged 15 grams compared with 13 grams in the experimental series. In the control series 31 or 91 per cent, had lung metastases while 18 or 90 per cent, of the ex perimental series had lung involvement. Skel tal metastases were observed in 74 per cent

of the control series and in 75 per cent of the experimental series. In this experiment like the preceding one in which the biopsy speci men was not a factor in the mass of the growth no difference was detected in survival time or percentage in which lymph node lung or skeletal metastases were observed

### COMMENTS

The concept held by many clinicians that a biopsy may enhance the growth of a neoplasm has long needed further investigation. It is generally recognized that it is often impossible by inspection alone to distinguish benign from

malignant tumors hence it is usually necessary to obtain a blopsy specimen. If phy sicians were to avoid incising suspicious le sions to obtain a bropsy then the early diag nosis of cancer would obviously be impossible. Unfortunately it is difficult to evaluate the effect of traums on malignant tumors of man since the heterogeneous hereditary patterns of the hosts differ and the observed tumors seldom are identical in either their gross or their microscopic features.

In the observations recorded here in which homogeneous strains of inbred rats were in oculated with equal portions of the same transplanted tumors one could ascertain the effect of surgical trauma on the neoplasms. It is noteworthy from examination of Table I that if one removes a portion of a tumor he increases the length of life of the animal this increased survival is due presumably to the decrease in the quantity of cells available for growth. Such data confirm the recent clinical observations (10) that the surgical removal of all available tumor tessue in a seemingly hopeless case serves to prolong the individual s life for several years Further no untoward effects are recorded by cutting into the tumor mass or by severing lymphatic channels. A survey of these reports and a study of the data reported here would suggest that the treatment of a neoplasm is facilitated by the removal or destruction of any quantity of the growth and that the hosts survival is, thereby proportionately prolonged.

### BUMMARY

 Rate bearing transplanted fibrosarcome, adenocarcinoma, and squamous cell cancer were operated upon and compared with an unoperated upon control series for length of sur vival after transplantation and percentage in which metastases were detected.

2 The average survival period of rats bear ing transplanted fibrosarcomas was significantly prolonged by excession of the tumor o days after transplantation but the percentage of lung and lymph node metastases was not altered.

3 The average survival period of rats bear ing transplanted adenocarcinoma was significantly prolonged by the removal of a considerable mass of the tumor 60 days after in oculation The rats operated upon which survived the rats of the control series had a significantly higher percentage of lung met astases.

4. A simple biopsy performed on rats bear ing transplanted adenocarcinoma did not af fect the average survival period of the rats or increase the percentage with lymph node and lung metastases.

5 A simple biopsy of transplanted squam ous cell cancer did not affect the average sur vival period of the rats or increase the per centage of metastasis to the lymph nodes, lungs, and skeletons.

# CHRONIC OSTEOMYELITIS COMPLICATING WAR COMPOUND FRACTURES

An Evaluation of 125 Patients Treated by Early Secondary Closure

THOMAS HORWITZ, M.D., F.A.C.S., Colonel M.C. A.U.S. Ventnor New Jersey and RICHARD G LAMBERT Captain, M.C. A.U.S., Hines, Illinois

THE remarkable success observed fol lowing delayed primary closure of war wounds on or after the fourth day following initial débridement and of late secondary closure following excision, either by direct suture or closure with skin flaps or grafts (Churchill) stimulated our efforts toward early closure of wounds in the treatment of chronic osteomyelitis complicating war compound fractures. We adopted a plan of conservative ostectomy followed by wound closure on the fifth postoperative day in cases in which such closure was mechani cally possible and appeared warranted and penicillin was used both systemically and locally

Observations, herein recorded and initiated September 15, 1944 have been directed toward answering the following questions

- I What is the value of penicillin systemically and locally, in war osteomyelitis?
- 2 What is the optimum time for ostectomy? 3 What shall be the extent of the ostectomy?
- 4. What is the value of early secondary wound closure not only in diminishing the immediate convalescent period with a mini mum amount of scarring and deformity but in preparing the field more adequately and more quickly for definitive reconstructive work, when such surgery will be necessary?

On our service we have accepted a minimum waiting period, following cessation of all drain age, of 3 months prior to definitive soft tissue reconstructive surgery and of 6 months prior to reconstructive bone surgery and we are convinced, following our own experience and that of others that shorter periods invite an

increased incidence of recurrent infection. Despite our anxiety to reduce this time factor we do not accept the method of widespread extirpation of soft tissue and bone recently advocated in the treatment of war osteomyelitis, as the drive to eliminate infection surgically appears greatly to exaggerate the already existing soft tissue and osseous reconstructive problems (Kelley Rosati and Murray)

TECHNIQUE

Soft tissue is not sacrificed indiscriminately. The sinus tract and necrotic skin margins are excised and the ostectomy is limited to the removal of bone that is obviously dead and detached. Any bone that appears viable is spared. Sharp edges and prominences are not removed except when they might interfere with wound closure.

The skin is undermined freely In some cases this procedure has been carried to fully one-half of the circumference of the extremity However, there has been no spread of infection by such extensive dissection. It often permits complete skin closure or at least a considerable diminution in the size of the wound gap Mattress sutures of silkworm gut or wire are used in conjunction with buttons to prevent cutting in of the skin. The upper and lower portions of the wound are closed and the central portion is left open one or two sutures being placed in readiness for closure on the fifth postoperative day.

A vascline gauze or rubber drain is inserted into the depths of the central portion of the wound and plaster of Pans fixation is applied Usually the posterior one-half of the previous cast is utilized and completed with a few circular bandages. On the fifth postoperative day the drain is removed through a fenestrum and the sutures are closed if the appearance of

the wound warrants it. These sutures are removed on the tenth postoperative day and the cast is closed for 1 month. Subsequent external fixation will depend on the appearance of the wound and the progress of bony union.

Femur cases are returned to balanced suspension with skeletal or skin traction depending on the state of bony union.

In cases in which complete skin closure has not been possible or advisable, healing of the residual skin defect has been materially hastened by the early application to receptive surfaces of either split skin grafts or large pinch grafts

There have been some cases with extensive loss of soft tissue in which this method of delayed with approximation has not been applicable Here the extensive surfaces have been covered, even in the presence of considerable drainage, with intermediate skin or pinch grafts. In some of these cases, in which the defect has existed over bony prominences or easily traumatized areas or in the preparation of the field for definitive reconstructive measmers, more adequate skin coverage has been found necessary following this temporary skin dressing

Dose of penicillan Systemic. Penicillan has been employed intramuscularly in 15 000 to 30 000 unit doses every 3 hours beginning at 6:00 p.m. on the evening prior to surgery and has been continued postoperatively for a minimum of 10 days. Total dosage has varied from 1 200,000 units, in mild and moderately severe cases, to 2,400 000 units in the severe cases of esteomyelltis. More recently a uniform dosage of 40 000 units every 4 hours has been adopted (Keefer et al.) Our patients have invariably preferred periodic intra muscular injections to continuous administra tion by vein or muscle. The antibacterial agent was discontinued in 6 patients because of severe skin reactions, without mishap and there were 3 instances in which a clinical pic ture of nonspecific reaction was manifest toward or shortly following the completion of the course of penicillin-reactions attributed to impurities in the commercial preparations

Local Pentellin instilled in 20 cubic centi meter doses 3 times daily (250 units per c.c. of sterile water) was employed in the irst group of 75 cases, a 3 inch rubber tube having been introduced through a stab incision into the depths of the wound. This treatment was eliminated in the second group of 50 cases for purposes of comparison.

### EVALUATION OF CLINICAL MATERIAL

Series A consists of 75 cases of chronic osteomyelitis treated by ostectomy and delayed closure and the use of penicillin, both systemically and locally between September 15 1944 and March 1 1945 and evaluated up to September 15 1945 (Table I)

Of this group in 73 patients (97 2%) the wounds are completely headed while in only a cases (28%) are they still draining. It will be observed that in 41 cases (24.7%) healing was complete within a months and that wound healing occurred in another 31 cases following drainings periods up to 9 months a total of 72 healed without reoperation. One patient with involvement of the os calcis was reoperated upon following a 10 month postoperative draining period. Several well localized sequestra were removed the cavity waits col

lapsed, and the wound healed 10 days later Of the 2 patients with persistent drainage fol lowing initial ostectomy one with a localized osteomyelitis of the femoral neck has been reoperated upon 7.5 months later while the other with extensive infection in upper end of tibla and knee joint draining 8 months after operation may require a second ostectomy 1

Total

Cases of ostcomyelitis at the ends of long bones with adjacent joint involvement have proved to be very recalcitrant. In one patient with chronic infection at the distal end of femur and involvement of the have joint healing occurred after 8 months of postoperative drain age in another with involvement of distal end of tibia and analie joint healing was complete o months postoperatively

Series B consists of 50 patients treated in like manner but without local penicillin. Ten patients were operated on between September 15, 1944, and October 15, 1944, and the remaining 40 between April 14, 1945, and July 6, 1945, all have been evaluated up to September 15, 1945 (Table II). In this series B, wounds are completely healed in 46 (92%) patients, and in only 4 (8%) are they still draining. It

will be noted that in 45 cases (90%) healing was complete within 2 months after operation

No significant information has been obtained in an evaluation of the theaters of operations from which our patients have been derived. This observation also applies to the bacterial growths obtained from the wounds which revealed several types of penicillin sensitive staphylococci and/or streptococci, with a variety of other organisms which were often insensitive to penicillin. The latter groups did not appear to inhibit wound healing materially, although contributing to the amount and odor of drainage, and they tended to disappear as healing progressed.

### EVALUATION OF STUDY

I Value of penicillin A comparison of the progress of wound healing in those patients treated early in Series A in whom penicillin was first employed very cautiously and in total doses from 250 000 to 750 000 units, with those treated later with more adequate total doses (1 200 000 to 2,400 000 units) has convinced us that penicillin, systemically administered is of definite benefit in the treat ment of this type of chronic osteomyelitis Although our operative technique has not varied in these cases there are other variable factors present which make the evaluation of penicillin a purely relative one and not accurately measurable viz. the duration of pre-

Both cares crased draining to 3 months following respectation. I sthey words, healing has occurred in all 78 cases, or no to cont.

Postoperative Drainage Period

operative delay the severity and extent of the fracture and of the complicating infection and the anatomic site of the infectious process.

It is believed from a comparison of Series A and B that the local use of this agent has not served materially to alter the progress of wound healing and for this reason its local use has been discontinued. Thus the nursing problem required by repeated local instills tions is eliminated.

2 Optimum time for extectomy The value of adequate preoperative delay. Our patients have

often required whole blood for secondary anemia and a diet high lin protein and vitamin C Extensive drainage has been materially lessened during this waiting period by a preliminary course of penicillin. Elevation of the affected extremity has diminished edema and simple exposure of the wound has served to improve the condition of the soft tissues which are often macerated and inflamed from prolonged exposure to drainage. Adequate preoperative delay which has been tolerated well in all instances, not only encourages improvement in the patient's general condition but insures more accurate delimitation of the infection and permits progress of bony union

A study of the figures in Table III and of the graphs in Chart i demonstrates a striking relationship between the duration of the pre operative and the postoperative drainage periods and the incidence of large bone defects and/or disturbances of bony union

In an analysis of the 73 healed cases in Series A, most rapid postoperative wound healing (10 days) occurred in those with the longest preoperative delay (average months) This must, therefore be interpreted as the optimum waiting period in this series It will be observed that as the period of delay prior to ostectomy has lessened the period of postoperative drainage has lengthened and the incidence of bone defects and of nonunion has mounted In other words adequate preopera tive delay encourages a shortening of the post operative drainage period which means lessened soft tissue scarring. It also ensures more accurate delimitation of the bone infection which in turn permits easier definition and less sacrifice of bone by the surgeon at the time of ostectomy less residual bone defects and a greater likelihood for firmer bony union.

It may be argued that, for example a preoperative waiting period of 2 months with postoperative drainage for 4 months represents no greater loss than a 4 month waiting period with only 2 months of postoperative drainage. This is far from true for the case with the shorter postoperative period of drain age will show healing of soft tissues with less scarring will probably have had less bone sacrifice at the time of sequestrectomy and bony union will be more secure

2. Extent of ostectomy Conservative bone excision Only bone that is obviously dead and detached is sacrificed. Prominences and irregularities are not removed except when they may interfere with wound closure Protruding bone is excised to the level of the surrounding granulation tissue Bone thus spared may aid materially in diminishing the problems of bone defects and of delayed union The wisdom of this attitude is exemplified in an early group of patients in Series A in whom all apparently infected bone was resected boldly, with resultant bony gaps, shortening and deformity, and with prolonged drainage notwithstanding and who have been faced with extensive programs of reconstructive surgery. We dislike the term saucerization? in the surgery of these cases for the creation of a saucer like topography of necessity im plies the sacrifice of adjacent normal bone and the exaggeration of pre-existing defects

We have observed that extreme conservatism must be exercised particularly in the excision of bone in certain regions, as for example in the lower end of the femur, the upper end of the tibia and in the os calcis Indiscriminate resection because of the lack of adequate bone reformation in these particular areas serves to create considerable reconstructive problems prolongs convalescence and delays functional restoration. We have observed a number of these cases given sufficient time fill in spontaneously with scar, while the residual column of bone has been sufficiently sturdy to assume adequate functional responsibility. Thus far only a patients with upper tibial defects will require plastic reconstructive measures of any magnitude Collapse of the walls and elimination of the cavity appear worthwhile in selected instances of chronic osteomyclitis of the os calcis

A few areas of which the ilium and fibula are examples lend themselves very well to a liberal extirpation of involved bone since this sacrifice leads to no disability whatever yet often ensures successful delayed closure.

4 Value of delayed wound dosure. The extensive undermining of skin performed to permit a complete or partial closure following estection; has not resulted in the spread of infection in any instance. This procedure

offers a rapid method of closure with adequate skin, lessens the need for skin plastic measures ensures less scarring and a more satisfactory bed for reconstructive surgery of underlying muscle tendon nerve and bone

### CONCLUBIONS

- r Penicillin, administered systemically in adequate doses, as of value in the treatment of chronic osteomyelitis complicating war compound fractures. Its local use has not assisted materially in wound bealing and has been dis-
- 2 The purpose of early skin closure follow ing ostectomy in the treatment of war osteomyelitis is to encourage healing of these wounds with the least amount of scarring and deformity. This result is obtained most ideally when the skin flaps may be coaptated directly as herein described
- 3 Adequate preoperative delay ensures a more accurate delimitation of the infectious process. This serves to lessen the amount of bone that need be sacrificed at the time of ostectomy and allows for progression of union at the fracture site for if this is secured.

the treatment of the osteomyelitis becomes considerably simplified

4 These factors—the healing of soft tissues with the least scarring and deformity the sacrifice of the least amount of bone and the occurrence of union at the fractive site—all serve to lessen some of the more complicated problems in the reconstructive surgery of extremity war wounds.

It is our firm belief and our statistics bear this out that the conservative approach berin described assures greater likelihood for the satisfactory control of war cateomyelitis serik the least sacrifice of soft tissue and bone. Other methods in use elsewhere where the drive to eliminate infection carries with it the wide spread extirpation of soft tissue and bone, serve to esaggerate and complicate the reconstructive problems already present in these cases.

### PERSISTENCE OF THE VITELLINE (OMPHALOMESENTERIC) ARTERY AS A CLINICAL PROBLEM

H. G SMITHY M D., and I ALLEN CHAMBERLIN M D Charleston South Carolina

EVELOPMENTAL anomalies originat mg in the embryonic vitelline or omnhalomesenteric structures are pre dominantly those as occated with Meckel's diverticulum. Much less common than persistent elements of the vitelline ductal system are anomalies arising from the vitelline vascular system Despite their rarity persistent omphalomesenteric vascular remains were recognized and described in the latter part of the eighteenth cen tury That they may be of singular importance as a clinical problem is attested by the ensuing discussion EMBRYOLOGY

Review of the embryologic development and

consequently of persistent anomalies of the vitel line (omphalomesenteric) circulation begins with consideration of the yolk sac. In the human em bryo the volk and sometimes called the umbilical vesicle is demonstrable in the earliest known specimens i.e. at the end of the second week (11) Its nutritive function is probably of minor significance but its entodermal lining gives rise to the mucosal enthelium of the major part of the digestive tract while the mesodermal layer of its wall is the site of early development of blood cells and vascular channels (1 3) Primitive blood islands of the vascular anlage have been demonstrated in the mesodermal layer of the volk sac wall of the Peters and von Spee embryos (131/4 to 18 days of age, 12) As the yolk sac enlarges and as the prim itive gut develops the two structures become connected to one another by the so called volk stalk, or vitelline (omphalomesenteric) duct, which elongates as the embryonic body increases in size Subsequently the yolk sac atrophies and the vitelline duct becomes incorporated into the um bilical cord. It detaches itself from the gut during the sixth week of intrauterine life. Normally the duct degenerates after its detachment. However persistence of its intra-abdominal portion occurs in 2 to 3 per cent of cases, manifesting itself definitively as the familiar Meckel's diverticulum of the ileum.

Like the vitelline duct, existence of the vitelline circulation is transient. At the fifth week of in

From the Departments of Surgery Medical College of the State of South Carolina and Roper Hospital

trauterine life the omphalomesenteric artery is the most prominent ventral branch of the aorta It arises from the latter by several roots and passing ventrally toward the umbilical cord di vides to surround the primitive gut by an arterial ring at the point of junction of the gut with the omphalomezenteric duct (Fig 1) In its subse quent course, it is paired so that two vitelline arteries are identifiable in the early embryo (s weeks) The paired vessels leave the embryo accompanied by the vitelline duct and are distributed as a ramifying plexus over the surface of the yolk sac. Coincidentally with atrophy and degeneration of the volk sac, one of the paired vitelline arteries disappears. The remaining one develops further and comes to lie in the mesentery of the midgut, supplying the latter with blood and becoming definitively the superior mesenteric artery (Fig 2) According to Cullen Its connec tion with the umbilical cord may persist long after the vitelline duct has disappeared, which nor mally occurs at approximately the sixth week of intrauterine life. Whatever may be the temporal relationship the vitelline artery normally loses its umbilical attachments to remain as the supe nor mesentenic artery

The vitelime veins arising in the wall of the yolk sac, are paired. The two vessels enter the abdominal cavity of the embryo at the umbilicus accompanied by the vitelline artery and duct From the umbilious the two venous trunks course cephalad, following the path of the gut to empty into the primitive heart. At the fifth week of embryonic development, the liver bud begins to expand and interrupts the vitelline veins in their course toward the heart. One of the vessels be comes incorporated for the most part in the growing hepatic sinusoidal system while the other atrophies and disappears. The surviving vessel receives the superior mesenteric vein and the splenic vein just before entering the liver and becomes finally the portal vein.

### CLINICAL SIGNIFICANCE

Persistence of the omphalomesenteric artery manifests itself anatomically as an adventitious intra-abdominal cord covered by peritoneum. Usually it is attached firmly at its two extremities

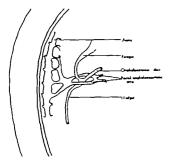

Fig. Origin of paired omphalomesenteric arteries from primit! sorts in the early embryo (5 weeks). Not relationship to junction of the omphalomesenteric duct and it testine.

one to the anterior abdominal wall at the umbilcus and the other to the mesentery of the terminal ideum. By such an arrangement there is formed a tense band traversing the abdominal cavity in an anteropostenor direction. Its potential danger as a source of intestinal obstruction is obvious. Per sistent viteline arterial remnants may be associated with a Meckel's diverticulum, in which instance a free band is formed connecting the diverticular mesentery to the unbillians or to the ileal mesenters to the unbillians or to the ileal mesenter; the resulting anatomic arrangement is a ring or loop through which coils of in testime may pass to become stranquisted. The least common form of persistent vitelline arter is that situation in which the vascular remnant is attached only at its mesentence end, the remainder of the vessel hanning free in the abdominal cavity.

Clinically it is significant that only 4 cases of persistent omphalomesenteric artery producing no symptoms have been reported. Of these only one was an adult, a dissecting room cadaver studied by Derbes and Hoge showing both per sistent artery and Meckel a diverticulum the case record contained no mention of abdominal ducomfort during lue. The others were infants examined at autopsy in 2 of whom the anomalous vessels were unattached at one end hanging harmlessly free in the abdomen (Meckel and Ruge) while the third was a newborn child found to have both meanters; and umbilies) attachments intect (Gesil) Inasmuch as 3 of the asymptomatic patients were infants at is striking that the liter ature provides only one adult patient showing no clinical disturbance as a result of persistence of the vitelline artery

Table I contains a summary of the literature of 12 cases of persistent vitelline artery in which disturbing clinical symptoms were present. Nine of the cases terminated fatally a mortality rate of 75 per cent. All but one of the deaths were due to acute intestinal obstruction. The retraining fa

Fraser and McCartney presented a small area of granulation tissue in the umbilicus. Actual cauterization of the granulating surface was

examination were confirmatory of a diagnosis of acute intestinal obstruction. Exploration of the abdomen revealed a stout cord attached at the umbilicus and passing posteriorly to disappear in the retroperitorical tissues just below the third portion of the duodenum. In its course, the cord had encircled a segment of intestine causing com plete obstruction of the closed-loop type. The patient died on the fifth postoperative day Histologic studies confirmed the presence of venous elements in the adventitious band.

Roper Hospital No. 50778. A Negro laborar 35 years of some range and respect to the heapful June 20, 1925, complaining of abdominal pain of 6 months duration. He stated my to accentance your as a monthly marked. My mark that his pain was intermittent in character located in and that his pain was intermittent in character located in and around the amblicus and in the expantic middle between around the minimum and in the epigeants, minimum occurrent the riphoid and the navel. The pull was constrained by the appears and the marks. And pull was causationed to standing, with, straining, coupling, and remaining erect (or long periods of time. It was said to be completely coer in sea persons or time. At was man to be competently reclined by reclining. For this reason, the disconfinet was noticed rarely at alght. Near the end of a day's work, the notices revealed that the pain was at its word and that pounting occasionally occurred under such directioners. There was no radiation of the pain and it was not influenced There was no radiation of the pain and it was not innecessed by eather or hunger. There was no history of hundredness, bloody or tarry stood, Jamelice, constipation, or diarrhedness, the other body systems was accountinatory partially assumed as a supportant of the other body systems was accountinatory panels.

Physical examination revealed the following temper-Project crammature revenue; the resourcing temperature of both pressure, 140/75 pulse and respiration portrail. The patient was a well developed and will four manner, the process was a real accordance and were some since distress but obviously in pain. Abdomen as flat and moved with respiration. There was non-standard was not and noticed with a part of the control of the parabolic. Tendences was present on pressure upon the parable. Tenderness was present on presents upon the middless but was not excessive rebound pain was absent. On succeitable, peristable was audible and of normal character. Rettal cammination was negative. Remainder of middless and only involved the relief of the characters are absent only involved to relief.

Laboratory studies showed white blood cell count 9,300 ABDURATORY REDGES REPORT WHILE DESIGN CONTROL WHILE WHILE DESIGN CONTROL DESIGN TO FRANCE WHILE DESIGN TO THE PROPERTY OF THE with normal outercome training to the configuration of gratic con-Onnayes sowed normal article. Analysis of gastric contents showed normal fadings. A specific diagnosis was not made but in view of the A specific transposes was not make out in view or ter-peraturni nature of the patient discomfort and because he persurent nature or the patient discomport and because ow was incapacitated by his illness, inperciousy was done 3

was management by me more, aparomeny was over a days after admission.

Under again anesthesis, the patient's abdowen was metered through a night paramedian incision. A firm, excurrent natural a sign parameters measure in many and tremely test abrous cord, covered by personeum, was found attached at one extremity to the under surface of the modifices and at the other to the secretary of the terminal issum a commencer from the discretal function (Fig. 3).

The bend did not enter the issum of the issum. Discretion And the meanteric attachment revealed the terminal portion of the cord to fan out into numerous small, fibrous, filamenos me conq to ma our mon minerous seaso, ma ous, mannerous strands which lost themselves between the two leaves tors sometime when was transmission or twent use two nature of the memoratery (Fig. 4). The main cord looped over the flerm to the latter in such a way as to support in neum to the set of the terminal fleum and occum when the part can wegat to the beaming beam and cream when the patient was referred (F. 3). However, there was found to be no against along of the less sense to the covering of the no aggregatation or the mean serious to the covering or an adventitions hand so that there was no evidence of obstrucautrentision issue as that time was to expected a desirec-tion or compression of the intestine — Furthermore, the cord

was not adherent to any other viscers along its course to the was associated as any other, reaction among its course to use timbilities. Traction upon the anomalous structure at in omoracon. Alaction upon the anomatom sourcine at in leocreal extremity caused displane and inversion of the multiture as observed from without. Further explanation national as observed from minutes a most capacitative revealed no abnormalities of the abdominal viscent. Then was no Meckel's diverselym. The cord was camped and Harted at its two extremittee and excised in its critical agazen as its two extremines and extreme in its convey and the abdomen was closed in Layera

Follow-up examinations at 4 and 10 weeks after operation have found the patient to be entirely free of pain. He has nave round me papers to be entirely free or pa-returned to work and is considered to be cared.

Pathologic examination of the removed specimen, which Assumed a continuence of the control of the control of the continuence in length, revealed a lough cord measure y continuents to singui, revenue a cour core covered by periloneum. Microscopic study of the sections coverious permanenta, anaroscopae suscry or the actions, selected from various segments of the cord, demonstrated a centrally located, thick walled, patent artery surrounded term any accurations where a layer of more compact by a zone of loose fibrofatty tissue a layer of more compact of a control around these and an external overing of around the control around the control around the control overing of a control overing overing overing overing overing overing over a control overing overi (T.E. 5) Higher magnification of the central artery showed (18 s. 5) suggest magnifestation to the course marry married as well defined internal charic lamina and a patent lamina containing red blood cells, some of them in rouleur

The occurrence of abdominal pain in this pa tient was apparently on a mechanical basis. Review of Figures 3 and 4 explains the traction type of discomfort which was noticed only when the individual was standing erect. In this position the gravity effect was such that the full weight of the cecum and, most probably several loops of small intestine, in addition to the terminal ileum, was exerted upon the adventitious band. This in turn produced traction upon the peritoneal surface of the umbilicus. In the recumbent position tension of the cord was reduced materially and the umbilical traction eliminated. Vomiting which was said to occur at the peak of intensity of the pain was more likely of the reflex origin, due to traction upon the periumbilical parietal peritoneum, than to actual obstruction of the bowel.

Of interest is the fact that no symptoms refer able to the abdomen occurred until the patient was 35 years old. While difficult to explain, it is significant that the patients reported by Mahomed and by Buchanan and Wapahaw developed their first symptoms after 18 and 12 years respectively Postoloff's case was 36 years old before noticing abdominal discomfort. On the contrary Shaw's patient, who was 43 years of age had suffered from lower abdommal pain since childhood.

Intestinal obstruction is the most common (and most serious) complication of persustent omphalomesenteric vessels. That no evidence of fleus was found either at operation or in the patients history may be regarded as coincidental. In respect to the production of symptoms by vitelline vascular remains in the absence of mechanical obstruction, the case is similar to those reported by Shaw and by Gautier It is probable that intestinal obstruction would have supervened

SMITHY ET AL. eventually if the adventitious band had not been

# A STUDY OF THE EFFECT OF PROPHYLACTIC ORAL SULFADIAZINE UPON INFECTION IN SOFT TISSUE

# WAR WOUNDS CLOSED SECONDARILY

STANLE1 O HOERR, M.D., Major M.C., A.U.S Boaton, Massachusetta

HE well controlled statistical studies of Meleney and his associates has cast serious doubt upon the efficacy of systems: suifonamides in preventing in fection in traumatic wounds. This present study on the other hand, although dealing with a somewhat different problem, indicates that sulfadiatine, given orally at secondary closure of soft tissue war wounds, reduces the incidence of infection and is associated with better healing.

The multiplicity of factors involved in wound healing makes the critical evaluation of any one factor difficult. It is difficult to carry out con trolled and impartial experiments in a laboratory the problems are greatly increased when one deals with patients rather than guines pigs and under war conditions it may at times appear impossible to obtain sufficiently accurate and detailed records, or observe the patient long enough to assess results. Furthermore, in the treatment of battle casualties the emphasis is upon producing the best immediate results by any and all means a relatively inocuous drug like sulfadiazine is likely to be freely used if it promises any concerv able benefit to the patient, rather than withheld in selected cases to help determine its true value.

In the treatment of the 200 soft tissue wounds which form the basis for this study it must be admitted at the outset that the aim was to procure the best possible results in each case, and not to conduct an experiment on the prophylactic value of sulfadiazine. The situation has been further complicated by the fact that in some instances penicillin as well as sulfadiazine has been em ployed prophylactically (Penicillin was not available for routine use in the light injuries which constituted most of the wounds.) Never theless, the very fact that wounds which promised difficulty were treated with prophylactic sulfadisting, lends weight to any differences which can be shown to favor the sulfadiazine treated group since it may be assumed that the bulk of the worst wounds will be included there.

From the Sargical Service of the Fifth General Hospital, APO 512, U. S. Army Read before the Society of University Surgeons, February 9, 945, New York, N. Y. It is perhaps worth mentioning at this point that little was expected from sulfadiante as a prophylactic when the series was begun in common with many other surgeons we regarded it with a skeptical eye. It was first med in those patients who had wound which promised trouble (as in deep wounds, or wounds which closed with considerable tension) or in whom good healing was of particular importance (as in wounds with associated damage of a peripheral nerve) Stock was taken after 150 wounds had been closed and the value of the drug appeared sufficiently established to warrant its routine use.

tablished to warrant its routher use.

It might seem from the difficulties detailed in the foregoing paragraphs that no valid coordu sions could possibly be drawn in this report. Some advantage may derive from the fact bow ever that the series is both consecutive and in every sense a personal one. The writer supervised the preparation of the wounds for closure, employed a uniform technique in operating upon them and personally observed their postoperative course. This at least eliminated the inevitable differences in judgment between ladividuals as to when a wound is ready to close, how it should be closed, and what constitutes a wound complication.

### MATERIAL AND METHODS

Material The series consists of 200 consecutive personally performed secondary closures upon soft tissue wounds in 131 soldiers 40 of the wounds were in 20 German prisoners of war 151 wounds were caused by high explosive fragments 47 wounds were caused by bullets, and a by nonbattle trauma. The wounds were all incurred in France and Germany between August, 1944, and April, 1945 In all but 7 wounds, preliminary debridement was carried out in forward bospitals and the potients transported to this general hospital anywhere from z to 25 days after the debridement. Compound fractures were excluded from the series, as were wounds in certain patients being promptly evacuated for other conditions (such as cerebral injury) which precluded a satisfactory period of observation. During this entire time it was the fixed policy of the surgical service

to close either by suture or graft all wounds at the earliest practicable time Recognized exceptions were wounds so small that they could be expected to heal spontaneously within 2 weeks, deep wounds with small openings wounds presenting severe and persistent infection (not more than 2 or 3 wounds were excluded for this last reason or a women were common for the was during the entire period). In general closure was preferred to grafting whenever it could be ef

Ninety three wounds represent a consecutive series for the entire hospital that is, every second ary closure performed in the hospital was carried out by the writer during this time, to prevent an artificial selection of easy cases for the sense. (Actually all wounds which promised difficulty in closure have been consistently turned over to the writer because of his interest in the problem.) The final results in the entire series are compar able to other published series of secondary closures Seventy-eight per cent of the wounds were solidly healed in 2 weeks or less.

Preparation of the mound. The appropriate time for closure was determined by the gross appearance of the wound. No closure was per formed at the first dressing but wounds which were clean when first seen were closed after a day or two of saline or azochloramide dressings. Wounds which were dirty or infected were treated with meticulous questings of 13000 sidicons solution of azochloramide once or twice daily at which time slough was picked off piecemeal. (In 3 or 4 cases a secondary debridement was necessary followed by secondary chastre a few days later ) Edema or induration at the wound edges was permitted to subside. Once the wound was grossly clean secondary closure was carried In some wounds appreciable delay in closure and even in the start of systematic preparation took place because of the press of more

Operative procedure. The procedure carried out depended entirely upon the physical character of urgent work the wound and fell roughly into one of three general types In those wounds supple enough to permit it (chiefly those received within 10 days of debridement) a simple closure was performed with widely speced deeply placed vertical mattress sutures of silk usually a heavy silk sutures were not buried Heavily scarred wounds were excised en bloc and closure carried out with buried sutures of fine silk or cotton and vertical mattress sutures of the same material to the skin There was an intermediate group in which there might he undermining of skin edges, or excision of exuberant granulation tissue, or modification of

<sup>\*</sup>Large wounds: these 6 can be more in length, or 3 can be more in width

location of the wound emphasis was placed upon supporting the suture line with adhesive strapping (which was often applied immediately after operation as well). Sulfadiazine was employed therapeutically, in 7 instances, and penkellin in 4 instances after infection had appeared in a wound. Their use in these cases has not been regarded as prophylactic although they may have contributed to the swifter healing of the wound. In 7 case particularly penfeillin appeared to abort a serious ceiluitis.

Appraisal of complications: This feature of the study is of paramount importance. Ideally, a single person, other than the surgeon, should follow all the wounds, since surgeons are some times reluctant to see blemishes in their own handwork. Unfortunately this ideal arrange ment could not be followed but the writer made an honest effort to be both strict and uniform in

applying critera of wound bealing and to note even the most minor compileations. Some evidence of strict interpretations is to be found in the fact that although 78 per cent of the wounds were healed in 2 weeks or less, 55 per cent are listed as having a compileation of one sort or another (Table I)

Complications were recognized as of two general types technical and infections. A hazr line may separate a "cutting sature from a mid attich abscens," or induration" (as seen a in a wound clored under tension) from 'moderate ceilulitis," although average examples in each group usually are clear enough. Wounds having both infection and a technical complication have been listed only once under the heading of infection. In each group of cases the wound was listed only under the most severe complication which it presented

The total healing time from secondary closure was determ ined for each wound Here again there was necessariance of the second was not as latitude in interpretation but a wound was not regarded as healed until epithelization was com plete In all but 2 or 3 instances the patient was kept under observation a sufficient length of time to determine the primary fate of the wound. In these exceptions the patients were transferred out 7 to 10 days after secondary closure, but healing seemed to be progressing normally at that time. In 5 cases, it was possible to record the onset of a at 5 cases it was present to account after apparent late complication a week or more after apparent sound healing of the wound It is necessary to point out, however that in many cases the development of a late complication would not have come to our attention since the patient Wil promptly discharged to duty when thought fit and readmission would have been more than

likely at another hospital. This is an important but unavoidable limitation of the study

ANALYSIS OF DATA The following facts stimulated the present study 44 wounds received no chemotherapy at the time of closure infection developed in 21 or 48 per cent 107 wounds received oral sulfadiazine at the time of closure infection developed in 23 or 22 per cent. The difference is statistically significant(r) Rather than being a final con clusion this fact can only be the starting point of a detailed investigation since in a series this small it might well be a result of an artificial selection of wounds, or the unsuspected operation of other factors. For example the 107 wounds in which rulladnzine was employed might have been the smallest soonest treated and cleanest wounds of

causes 2 from extreme tension and 1 from un obliterated dead space (not a hematoma) these three wounds have been also excluded from comparisons, since the failure was inevitable irrespective of a chemotherapeutic agent.

Tables II and III represent an analysis of the series as a whole from the standpoint of those factors thought most likely to affect the incidence of infection and delayed wound healing. The basic data are not very satisfactory in the category listed as chemotherapy at time of injury The data were taken from the individual field records. No account is taken of the duration of the therapy or of the dosages employed. In some instances perhaps only a single dose was ad ministered It is possible that some patients did not receive the chemotherapy that the record stated they were given it is probable that others were given some prophylaris (since it was Army routine) in spite of the fact that it was not men tioned on the record. In busy forward hospitals where the highest priority is given to the care of the seriously injured, errors in recording data

that have no great bearing on management of the lightly wounded are readily understandable. (Dates of injury and operation by way of con trast, are very reliable) Although there is an apparent increase in the incidence of infection in those who received no chemotherapy at the time of injury and although it is of great importance to determine its value further analysis in this paper is not warranted. It is of passing interest, however that what data there are are in keeping with the conclusions of this study (This holds true for German prisoners as well a majority of whom received chemotherapy when injured.)

Factors presenting significant increases in the incidence of both infection and delayed healing are the following wounds in German prisoners wounds yielding pathogenic bacteria when cul tured at the time of closure and finally wounds in patients who did not receive oral sulfadiasine at the time of closure. Perforating wounds, delay in closure of the wound or delay in preparing it for dosure, closure of the wound by block excision (usually related to delay) and failure to receive

chemotherapy at the time of the original injury all show significantly increased incidence of in fection but not of delayed healing

The apparent susceptibility of German prisoners to infection demands further investigation. Cross analyses of the principal factors affecting infection in this series with respect to each other (not shown in the paper) demonstrates that in each separate category there still exists a significantly increased incidence of infection in the group of German prisoners as compared with United States soldiers. The most natural assumption to make in connection with poor results in German prisoners, namely, that it is largely due to delay between time of debridement and closure (with resulting block excision of the wound) is refuted by Table IV which specifically compares the prisoners with United States soldlers on these two counts combined. Whatever the reason for the increase, whether debilitation, faulty nutrition or some other unsuspected cause, it is desirable to exclude German presoners from further analyses of the effect of prophylactic chemotherapy

Table V is an analysis of infection and delay cross analyzed by the location of the wounds. When corrected by excluding German prisoners, it can be seen that location is not a factor of much

significance in this series.

Tables VI and VII repeat the analyses of Tables II and III excluding German prisoners. Partly because there are fewer cases (and the per centage differences must be correspondingly greater to register as significant) and partly be-

cause most of the differences are actually less, the only factors which continue to show significant only across in the incidence of infection are the presence of pathogenic organisms in the wound at time of closure and the lack of prophylactic oral sulfadiazine at the time of closure. However ex pected trends in other factors are still discernible although not so marked. It becomes worthwhile at this point to cross analyze these influential factors separately from the standpoint of prophylactic chemotherapy at the time of closure.

In Tables VIII and IX the incidence of infec tion and delayed healing is considered from the standpoint of those factors appearing to favor their development as related to the use of oral sulfodiazane. Significant differences are not in dicated on these tables, because the break-down produces wound groups with relatively few wounds It is intended to show a trend however demonstrating a lower incidence of infection and retarded healing in the sulfadiazine-treated cases in almost every category. The only groups of wounds which fail to support this trend are those wounds requiring prolonged preparation and those wounds treated either by excision or revision and closure (This is also demonstrable

that should cause them to fall outside the general trend is not clear Further analyses are not enlightening, and it must simply be recorded as a

Table \ considers the problem of the serious infection In none of these patients did infection threaten life but in 18 wounds the infection was definitely more than trivial. There is again seen a sharp increase in the incidence of serious infection in German prisoners and again an increased incidence in those wounds not treated with prophy lactic sulfadiaxine There are insufficient cases to render the difference significant in either prisoners or United States soldlers considered separately although when they are combined there is a significant advantage for the group which re-

Table VI is a breakdown of the 73 consecutive ceived sulfaduzme wounds which were aerobleally cultured at the time of secondary dosure. It is unfortunate that all the wounds in the series were not cultured since the cultured group is not quite representa tive of the series as a whole (there is a higher incidence of infection than in the entire series) The common pyogenic organisms are considered TABLE DC.-EFFECT OF ORAL SULFADIAZINE ADMINISTERED AT TIME OF SECONDARY CLOSURE, CROSS-ANALYSIS BF PACTORS WHICH TEND TO FAVOR INFECTION AND DELAYED HEALING-GENIAN PRISONERS EXCLUDED

and again the analysis is subdivided according to the nationality of the patient. The numbers are so small that percentages have not been used, but the over-all trend slightly favors the wounds in which prophyractic sulfadazine was employed. Once more this is less convincing in the group of German prisoners apparently being a German prisoner had a more decuive effect upon the healing of the wound than any other factor concerned. Since as many as 5 wounds were closed at one sitting upon a single patient, and since the chemotherapy employed on the patient affected all 5 wounds equally, the objection might well be raised that it is utalair to treat the wounds statistically as separate from the patient. For example, 15 wounds on 3 patients not receiving sulfadiation might all become infected and they might all have been the result of three breaks in operating room

Staphylococcus agrees Staphylococcus albus and all atreptococci technique. This would obviously upset the entire series in a way not shown in the previous tabula tions. Table VII deals with the series as patients rather than wounds. (A discrepancy of 3 extra patients shown in this table is accounted for by the fact that in 3 cases wounds were closed at two alttings a week or more spart for the purposes of this analysis the patients were regarded as new patients at the second operation.) An infection developing in any of the patient s wounds causes developing in any of the patients a "fifection" that patient to be listed under "fifection" that patient to be listed under "fifection". The over-all similarly with delayed healing advantage for the sulfadiarine-treated patients is

once more demonstrated as a trend. The bulk of the cases not treated with sulfa diamne were in the early part of the series. A final objection might be raised that improved results came about as a consequence of better treatment of the later wounds (when experience was greater) rather than from the use of the sulfadiazine Of the first 75 wounds 30 received

no chemotherapy Infection developed in 13 of the 30 and there was delayed wound healing in II Of the second 75 wounds, 12 received no chemotherapy and in these 12 there was infec tion in 8 and delayed wound healing in 5 In the last 50 wounds 2 received no chemotherapy with no infection and no delayed healing. Al though the majority lie in the first 75 wounds a high incidence of infection also occurred in those wounds placed later in the series.

Numerous cross enalyses of the data have been made which are not included here. They have all followed the same general trend showing an ad vantage for wounds treated prophylactically with oral sulfadiarine. It is believed that all the contradictory evidence has been presented. DISCUSSION

Attention has been drawn to weaknesses in herent in an analysis of this particular group of wounds from the standpoint of the effect of

prophylactic sulfadiazine. They lie in the small size of the series, and in the fact that therapy was not originally planned as a research project. On the other hand, the series is personal, consecutive, and accurate observations on the fate of each wound are available—a set of circumstances not frequently met with where battle casualities are concerned.

A number of factors affecting wound healing and development of infection have been analyzed German prisoners were shown to have a high incidence of infection and delayed healing ir respective of other factors, and the bulk of the analysis has therefore excluded them. It has been shown that wounds which were excised and closed, or which had prolonged delay before closure did not appear to have a significant response to prophylactic chemotherapy the reasons for this are not clear Wounds in nearly every other category appear to benefit by a course of oral sulfadiazine given prophylactically at the time of secondary closure. The general trend is rendered more significant by the fact that by and large the worst wounds received chemotherapy on empirical grounds in the interest of obtaining the hest possible results. (Evidence for this state ment is the high incidence of infection and delayed healing in the small group of wounds in which

both sulfadiazine and penicillin were employed prophylactically)

Suggestive evidence that prophylactic chemically at the time of the original injury—days or week's before the patient reached a general hospital—decreases the incidence of infection after secondary closure was not pursued became of the likelihood of error in the recordings on the field record of the patients. A consideration of the value of topical sulfanllamide employed at the time of secondary closure is likewise beyond the scope of this paper.

It is recognized that the conclusion in this study is at variance with those of Meleney ar rived at in an elaborate statistical study of a much larger series of cases. The two series are not strictly analogous, however. These are wounds produced by the mussiles of war as opposed to wounds incurred through civilian traums. These are wounds in which closure is delayed deliber ately for days or weeks after infury as opposed to civilian wounds the vast majority of which can and should be closed as soon after the original injury as possible. Finally these are wounds in patients who have already received, for the most part, some type of prophylactic chemotherapy perhaps this early chemotherapy inhibits the growth of certain bacteria which lie latent in the

wound until stirred up by operative closure when they will produce infection unless inhibited again by another course of chemotherapy. Perhaps this early chemotherapy renders the wound more susceptible to infection at later operation than it would have been had no prophylaxis been used at all and the wound permitted to develop unaided its own local tissue immunity.

#### CONCLUSION

A personal, consecutive series of 200 secondary closures of soft tissue war wounds is analyzed

from the standpoint of the prophylactic effect of sulfadiazine administered orally at the time of closure.

The evidence presented favors the view that sulfadiazme so employed is beneficial and that it reduces the incidence of postclosure infection and delayed healing

# THE PELVIC AUTONOMIC NERVES IN THE MALE

FRANKLIN L. ASHLEY M.D., and BARRY J ANSON Ph.D (Med. Sci.) Chicago, Illinois

UMEROUS descriptions of the pelvic plexus of nerves are to be found in the literature. Although some of them are excellent neurologically none provides scrilally arranged liburations prepared from actual gross dissections. In the present article it will be the authors sole purpose to portray the structure of the pelvic plexus and associated nerves in atlas fashion, with description of related layers and organs.

#### LITERATURE

Anatomy According to Davis (1933 1934) the pelvic plexuses consist of interlacing groups of nerve fibers and of many but extremely small ganglia situated on either side of the ampulla of the rectum. The dimensions of each plexus are said to be 2 by 3 by 1 centimeter. The two plex uses are described as embracing the rectum in the manner in which the levator muscles embrace the anal canal. On each side the plexus is bilaminar the medial sheet being a continuation of the hypogastric nerve, the lateral a prolongation of branches derived from the sacral nerves. The two hypogastric nerves are joined at a lower level in the pelvis by parasympathetic fibers of the second to fourth sacral segments, these fibers making up the nervus erigens. The two contributions, together with sympathetic fibers from the pelvic chain ganglia, form the pelvic plexus.

The central connections, according to White (1935) are made up of preganglionic fibers from lower thoracic and upper lumbar levels of the intermediolateral columns of the spinal cord. Cells send out axones over the white rami of the lower thoracolumbar outflow to lumbar and preaortic ganglia. Postganglionic neurona originate in sympathetic trunks as well as in prescritic ganglia to form a plexus which descends with the abdominal aorta. At the level of the inferior mesentene artery are situated two small ganglis which, supplying a circumarterial plexus for branches of the inferior mesenteric artery ultimately innervate the sigmoid colon and rectum. The remainder of the descending sympathetic fi bers form the superior hypogastric plexus in the region of the bifurcation of the aorts. The plexus divides into two plenform sets of nerves which

Contribution No. 444 from the Anatomical Laboratory of Northwesturn University Medical School, Chicago, Illinois enter the pelvis, along its lateral wall as the hypogastric nerves (or plexuses)

Pelvic roots, forming the nervi erigentes, arise from medial aspects of the auteuro primary divisions of the second to fourth sacral nerves, 1 to 2 centimeters from their foraminous exits. They course to the pelvic pleasus, or directly to the rectum. Two or three fine twigs arise from each of the ganglia of the sacral sympathetic chain and enter the posterior border of the pelvic plems.

The urinary bladder receives sympethetic fiber from the collect, renal, and measureric agains, as well as from the first four lumbar ganglis of the sympathetic chain. These fibers, by way of the hypogastric plexmes, and in descent into the petvis, receive fibers from the last lumbar ganglis, from the infersor measureric plexms, and from the superior hemorrhoidal nerve. They also receive fine filaments from the sacral sympathetic chain.

The parasympathetic fibers (from scrat roots) first gathered together as the nervi erigentes, separate into three groups the upper supplies the funding of the bladder the middle supplies the midportion of the bladder and the lower course to the inferior aspect, the vesical neck, and the addrects portion of the urethra.

The cells of origin for these efferent fibers (parasympathetics) to pelvic organs lie in the intermediolateral column of the sacral region. The locations of cell bodies for the afferent fibers are so yet undetermined, but are probably in posterior root gaugin.

The prostate and seminal vesicles receive their innervation from the middle group of fibers while the rectum is innervated by the inferior group and by some fibers, which, remaining independent of the pelvic pleans, are sent directly from the hypogastric nerves and chain gaugits.

Physiology The sympathetica, according to Davis (1934) and Meigs (1946), behave as viso-constrictors and as inhibitors of the musculature of sigmoid colon, rectum, and bladder They cause circuistion and contraction of the spinote of the bladder Pseudosensory properties are regarded as vacomotor in foundation. The fiber are also glandulomotor to both superficial and deep visuals.

The parasympathetics produce vasodilatation and release of the various sphincters. They mediate pain sensation from the bladder. Section of

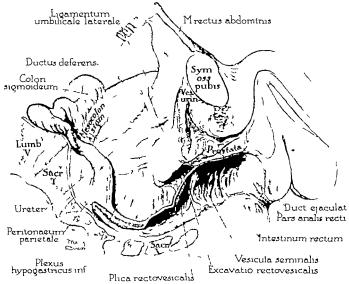

Fig. 7 Topography of the hypograstric plexus and related pelvic structures in a hemacated specimen peritoneal level (successively deeper levels of same specimen in Figs. 2 to 6). The left half of a male pelvis peritoneum intact. The action pames through the entire length of the rectum

and through the urinary bladder urethra, etc., and prostate (atter hypertrophied) The section also passes through the interpublic fibrocartilage, seminal vesicles, retropuble plexus of veins, scrotum, and penife cavernous tissue.

the superior hypogastric plerus does not cause atrophy, or disturbance of any motor functions of the bladder excusion of parasympathetics would cause increased blood supply to the pelvis, a diessening of visceral muscle spasm and interruption of pain impulses to higher centers. Schroeder (1939) quotes McCrae and McDonald (1934) as doubting if either system (parasympathetic or sympathetic) is exclusively excitor or inhibitor these authors believe the two work together and with somatic nerves, to regulate bladder function Let they are of the opinion that the parasympathetics are more important and that they carry the stronger impulses.

Surgery Jaboulas (1899) first directed attention to the fact that pain could be relieved by

surgery of pelvic sympathetics. Although Latar jet (1913) adequately described the pelvic sympa thetics, the first presacral neurectomy was reported by Cotte (1925) Pieri (1926) tried Cotte s operation for relief of pain in tuberculous cystitus finding the surgery only partly successful he next excised, with more satisfactory results, the lateral sacral chains at the level of the first sacral segment, and the communicating rami thereof Learmonth (1930) employed Cotte s method in an attempt to correct neurogenic imbalance of the bladder. More extensive reports were made by Davis (1933 1934) and Meigs (1940) on the relief of pelvic pain by presacral neurectomy Schroeder (1939) enumerates several operative procedures for relief of bladder pain excision of the superior

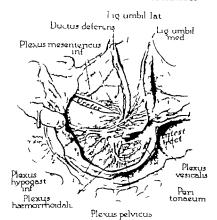

Fig. 2. Topography of the plermes, unter and doctor deferms immediately subpertioneal level. Showing the structure related to the pelviceon and return, namely surter Badder Biguanetts, and others. The parietal peritoneum of the lesser pelvis has been removed, and, additionally, the vesical part of the videral peritoneum. The senson layer remains as the pelvic mesocolos, the covering of the colon and rectum, the rectover of fauch and also as the binaminar seption which descends between the blad der and rectum and rectum (fascia of Demonvillers marked by arrow here and in Fig. 7. The oreter doctors deferen, unbibliod Biguaneti (obliterated artery) and nerves have been freed from the thin stratum of subpentional areolar tissues.

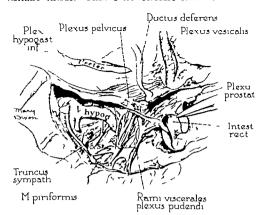

Fig. 3. Relation of the hypogratic plexus to the terminal vesscal plexus, and to the deeper rami derived from the acropulential plexus. The latter are situated at parietal level. Depecting the rectum urinary bladder ductus deferens, ureter pelvic autonomic nerves, and related structures. The following have been removed pelvic colon proximal part of rectum (dustal segment retracted) superficial leaf of autonomic nerves to the point of severance of the rectum (opposite fifth sacral vertebra). The nerves are followed toward the rectovescal excavation the ductus deferens is modifized as far as its point of junction with the seminal veside where the associated nerves Be within the rectovescal fold. The hypogratic and plated veins are exposed. The sacral sympathetic chain with communicating fibers from the second to the fourth sacral, is exposed, as a also the sublacent piriformis muscle. The layers shown are in succession. Hypogratic and pelvic plexuss lodged chiefly in subperi toneal areolar tissue heavy retroperitoneal connective tissue, upon which the visceral branches of the above named plexuses rets or through which they pass visceral rams of the sacropodendal plexus of nerves musculature (pariformis, passing from the secrum through the greater staits formacm).

nerves and related structures they were prepared at his size.<sup>1</sup> An accessory illustration (Fig. 7) reduces the nerves to a schema. The diagram matte sections (Figs. 8 and 9) are based upon a coronally cut pelvis of a second male specimen Between the prostate gland and the rectum it descends as a partially fused plate of tissue termed Denonvillers fasca (arrow Fig. 1).<sup>2</sup>

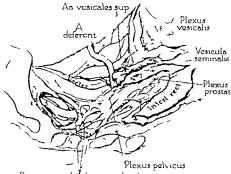

#### OBSERVATION AND DISCUSSION

Persioneum. The persioneum is elevated by the obliterated hypognastric (umbilical) artery slightly by the superior vesical branches derived therefrom and by the ductus deferens and ureter (Fig. 1)

Comparable strate in the female polymewre illustrated in an earlier article (Figs. to 4) Cartis, Assen, Askley and Jones, 04.)
The reader is referred to the excitent article on Deceavallers fascia by Tobia and Benkincin in an earlier volume of this paral.

The rectovesical fold is prominently tall it is little more than apposed layers of peritoneum projects i centimeter backward from the bladder the excavation which it guards is 1 5 centimeters deep, measured from the edge of the fold to the depths of the rectovesical excavation. The transverse vesical fold is but a slightly elevated part of the peritoneum. The lateral umbilical fold has a maximum height of 1 5 centimeters (at the public crest), the fold is flattened so that its space opens lateralward.

The pelvic colon possesses a mesocolon which is 6 centimeters long where the colon reaches the midline over the fourth lumbar vertebra (Fig. 1) the mesenters becomes gradually shorter being 2 centimeters long in the true pelvis opposite the first sacral vertebra fixation occurs at the level

Rami viscerales plexus pudendi

Fig. 4. Form and composition of the deeper leaf of nerves. Showing the pelvic plems, the superficial leaf of which has been entirely removed to even be deep layer of the pelvic a tonomic plems and the nerves contributing to its f brie. The nerves from the second 1 fourth scard lettings i remain intext, and the anterior continuation of the pelvic autonomic plems has been followed ventralward to the bladder seminal vesical, and prostate. The rectum, transcrient at except level, has been retrained. The slarge reduced the rectum form of the pelvic autonomic plems has been followed when the level may be a large reduced to the rectum of the pelvic leaves the respect to the pelvic set of the pelvic leaves the respect to the pelvic set of the pelvic leaves the respect to the pelvic set of the pelvic leaves the pelvic l

of the ridge between the second and the third sacral segments. The pelvic colon is constricted through the greater part of its length. The rectum is similarly constricted as it lies in front of the third and fourth sarral pieces it widens slightly in front of the fifth, and further enlarges as it passes distalward beyond the arra of vertebral relationship. The narrowed anal canal leaves the rectum at an angle of almost 90 degrees. The three portions of the tube are then, related to one another as the parts of a letter Zreversed.

Subprenent structures The beavier retropen toneal (tissue which ascends on either side of the urinary bladder as a wing to that level, in projecting backward forms the plate of tissue over which the pertoneum is draped to produce the rectoverical fold (Fig. 2).

The observations on the general arrangement of subperitoneal tissue are in accord with those made earlier on the female (Curtis Anson, and

Beaton 1940 Vessels in the category of the bemorrhodals are lodged in a fine areotar layer which is immediately subpertioned, autonomic nerves coursing to viscens are next in level, becoming more superficial as they approach the organs parietal vessels are placed in the heavy connective tissue which is clearly "parietal" and with them are situated visceral rami most deeply placed, and actually retrofacial, are the elements of the sacral and lumbar plexuses, from which alter communicating rami are sent through the heavier retropertoneal tissue to reach the autoomic plexuses near the bladder and rectum.

The ductus deferent, areter and accompanying nerves lie within a thin areolar layer with the middle hemorrhoidal and associated sympathetic plexus (which give off rectal, vesical, and prostate sets of nerves). Still covered by tissue of areolar character but evident as elevations, are the "obliterated" hypogastic artery (lateral umbilical ligament) and its derived superfor vesical colligament) and its derived superfor vesical.

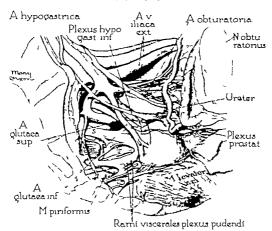

Fig. 7. Parasympathetic origin of the rand contributory to the pelvic piems, and deep structures related to the latter. The deep relations of the pelvic piems, also hypermoval of the plevic piems, aboven by removal of the plevic piems, aboven by removal of the piems and the beavy retrogeritoneal tissue which partially invests it. The transacted parasympathetic nerves (viscear rani) of the pudencial piems) remain connected with the sacral plevus the distal continuations of the automorales have been cut as they disappear beneath the pressate and serimal vesicle. The connections between the inferior hypogastric plerus and the pelvic plerus have been severed along the inferior margin of the former. All of the retroperitoneal connective tissue has been removed exposing the endopelvic fascia, the vessels and nerves to the pelvic viscers and parieties, and to the lower extremity. The connective tissue has been removed from the greater sciatic formmen to expose the full course of the nerves contributory to the sacral and pudencial plecuses and the larger vessels as they leave the pelvic. The superior fascia of the pelvic disphragm has been removed, exposing the levator and muscle.

branches. The outlines of the gluteal obturator middle hemorrholdal and pudendal vessels are masked by the heavy retroperatoneal layer

Nerses' Most important is the position of the several sympathetic pleanes (Fig 2 of Fig 7). They are parietal in position they do not immediately surround the organs as familiar textbook illustrations would lead one to believe. Actually the large middle hemorrhoidal is actually 5.0 centimeters distant from the rectum it sends numerous rami to the rectum, these passing posteriorly over an area bounded by the line at pelve mesocolic attachment (above) and the line projected (below) from the superior surface of the uniany bladder. In the erect body their direction would be horizontal, while that of the trunk from which they are derived would be vertical.

The deeper structures are chiefly related to the nerves of the intermediate and deep leaves (Fig 3) The intermediate leaf consists of the parasympathetic fibers of the second third and fourth sacrals and sympathetics which enter these just lateral to the chain ganglia. The parasympa thetics (nervus engens) intercommunicate form ing a small plexus which makes up a deep leaf The two layers meet approximately 3 centimeters lateral to the rectum Some of the fibers of the parasympathetic derived from the fourth sacral diverge medially to enter the wall of the rectum The intermediate leaf is separated from the deep (sacral plexus) by the large hypogastric vein and its glutes tributary The vein in turn crosses the puriformis muscle obliquely From the large gan glion resting upon the lateral surface of the body

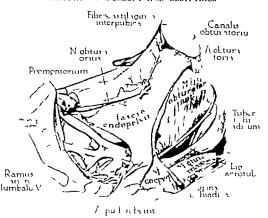

Fig. 6 are lybe—th then t=10 a possibility blees (cut)—in Japaicial of related to plantamate modes and (see 3 % of utroomly the remove). The graph partials of the large—resel ha. I been removed by goodly her proposed to the observation of the large—resel has been followed to be observed to the observation of real through the greater scattle featurent t=1; it of one ergors—of the trank t from the scattle of possibility of the content of the conte

of the first sacral vertel ra many small fibers course over the sacral artery and hypingal tric vein to supply these vessels, some reach, and supply the hypogastric artery and its branches. I rom each of the ganglia a gray ramus ommunicans may be seen paying deeply through the juli-tance of the pinformis muscle to the sairal nerve of it. corresponding segment. The deep leaf of perves consists mainly if the second third and fourth sacral nerves. At their points of emergence from the bony foramina the second is 0 5 entimeter wide the third is 0.4 centimeter and the fourth is 0.3 centimeter in width A distance of a 5 centimeters separates the second from the third 14 separates the third from the fourth. The height of the "arch" (measured transversely) between second and third is 2 o centimeters, that between third and fourth is a centimeter. At the point of union of the three components the band is 25 centimeters with (measured vertically)

The configuration of the Frankenhaeuser pleus and its comps next becomes clear when the super ficial leaf of nerves has been rem ved (Fig. 4 of Fig. 7). The sympathetic nerves fin superior and lateral origins f rm the inferior hypogastre pleus of hypogastre nerve thes are joined by the small pleus formed by the parawingsthetic nerves from the second to fourth sacrals. The two systems then blend into a single large flat hand overlying the deep vessels from the hypogastre. The shape is that of a large. I have sympathetics forming the lateral arm the parasympathetics, the medial. The fusion of the two continues as one large flat sheet composered of many nerve filters and sheaths of connective tissue. The flates and sheaths of connective tissue. The flates

urethra to innervate those structures. There is a separate group of small fibers which passes into the region of the seminal vesicle. Some fibers detach themselves from the plexus to supply the terminal portion of the rectum

The superiorly located fibers of the plerus pass beneath the seminal vesicle and the crooked por tion of the ductus deferens to enter the wall of the bladder. The lowermost, as previously men tioned, enter the rectum, and intermediate fibers continue to the prostate and membranous ure the

The distance from the mid point of the plexus to the lateral rectal wall is 3 5 centimeters. The length of the Y-shaped plexus is 8 centimeters (to the nerves at the prostate)

The parasympathetic nerves are five in number (Fig. 5 severed at the point of entrance into the plexus). The cranial two arise from the junction of the second and third sacrals the third arises from the third sacral, the fourth nerve from the fourth sacral entirely, and the fifth from the junction of the third and fourth. The plexus is prolonged between the rectum and prostate the plexus was previously described as an intermediate group of nerves leaving the plexus and entering the prostate, the inferior aspect of the bladder and the seminal vesicles. The inferior or caudal, group of nerves leaves the plexus to enter the ampulla of the rectum as three or four stems of gross dimensions.

l essels The hypogastric artery and its branches and corresponding veins he deep to the fascial layers which house the autonomic nerves (Fig 5) The most superiorly placed vessels are the external thac artery and vein. Next is the um bilical artery with its four vesical branches, all of which course first toward the superior surface of the bladder some then passing to the inferior The vesical arteries are lodged in an intermediate layer of connective tissue which covers the deep vessels and remains entirely separate from them The small deferential artery takes origin from the lowermost of the vesical arteries the ureteric ar tery also in this layer arises from the small vesi cular branch just above the one which gives origin to the deferential. Another small artery passes directly through the plexus to enter the tip of the seminal vesicle. The obturator arises by a com mon stem with the umbilical the gluteals descending leave the pelvis above and below the piriformis muscle. The inferior gluteal artery gives rise to the internal pudendal just before it

leaves the pelvis.

The vessels are internal to the endopelvic fascia (Figs. 5 and 6)

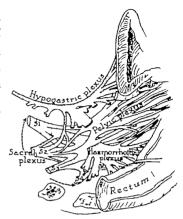

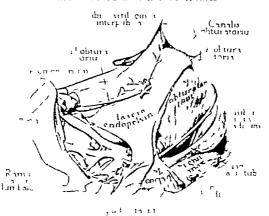

Fig. 7. Dagram of the pelvic pleans, showing origin and dustribution of the chief components, and their gross interrelationships. Medial aspect. The hypogastric pleans is shown intact in its curving course to the urinary bladder but has been cut away in that part which, overlying the pelvice pierus, contributes to the hemorrhoidal pleans. Between these two, and lateral to them, the fibers derived from the sacral nerves are shown streaming toward the bladder protate, and cand, rectum etc.

The endopeluse fascia The so-called endopeluse fascia is actually aponeurotte in nature Continued upon the levator am and coccygeus muscles the endopeluse fascia becomes disphragmatic fascia (Fig 6). Over the upper part of the obturator internus muscle it is parietal and when reflected from the peluse disphragm to the rectum and bladder it becomes visceral (cf figures in Curtis Anson and Beaton, 1949).

It is clear, then that the relations to fascial levels are of fundamental importance. In the heavy retropentioneal layer is located the large pelvic plexus, with its vesical and prostatic continuations (Fig. 4) into this layer sink the originally superficial fibers of the inferior hypogastric plexus (Fig. 2) and to it ascend the visceral rum originating from the sacral plexus of nerves (Figs. 3 to 5). In dissections this set of relationships is strikingly demonstrated when the heavy stratum is reflected (Fig. 3) as they enter the pelvis from above the sympathetic fibers are situated justs beneath the serous layers and upon the heavy

centimeters and (measured vertically) The intruration of the Frankenhaeus-ripleaus and it compenent becomes clear when the super ficult leaf of nerves has been removed (by, 4 d Fig. 7) The sympathetic nerves from uperar and Literal one n f im the inferior hypoca tra plexu or hypogastric nerve, they are joined by the mall plexus formed by the para empathetic nerves ir on the second to fourth sacrals. The two systems then blend into a single large flat hard verlying the deep vessels from the hypoga tric The shape is that of a large \ the sympathetics forming the lateral arm, the parasympathetics, the medial. The fusion of the two continues as one large flat sheet compared of many nerve filters and sheaths of connective tissue. The filers course toward the prostate Hadder and upper urethra to innervate those structures. There is a separate group of small fibers which passes into the region of the seminal vesicle. Some fibers detach themselves from the plexus to supply the terminal portion of the rectum

The superiorly located fibers of the plexus pass beneath the seminal vesicle and the crooked por tion of the ductus deferens to enter the wall of the bladder. The lowermost as previously men tioned, enter the rectum and intermediate fibers continue to the prostate and membranous urethrs.

The distance from the mid point of the plexus to the lateral rectal wall is 3 5 centimeters. The length of the Y-shaped plexus is 8 centimeters (to the nerves at the prostate)

The parasympathetic nerves are five in number (Fig. 5 severed at the point of entrance into the plexus). The cranual two arise from the junction of the second and third sacrals the third arises from the third sacral the fourth nerve from the fourth sacral entirely, and the fifth from the junction of the third and fourth. The plexus is prolonged between the rectum and prostate the plexus was previously described as an intermediate group of nerves leaving the plexus and entering the prostate the inferior aspect of the bladder and the seminal vesicles. The inferior or caudal, group of nerves leaves the plexus to enter the ampulla of the rectum as three or four stems of gross dimensions.

l essels The hypogastric artery and its branches and corresponding veins he deep to the fascial layers which house the autonomic nerves (Fig 5) The most superiorly placed vessels are the external iliac artery and vein. Next is the umbilical artery with its four vesical branches, all of which course first toward the superior surface of the bladder some then passing to the inferior The vesical arteries are lodged in an intermediate layer of connective tissue which covers the deep vessels and remains entirely separate from them The small deferential artery takes origin from the lowermost of the vesical arteries the ureteric ar tery also in this layer anses from the small vest cular branch just above the one which gives origin to the deferential Another small artery passes directly through the plexus to enter the tip of the seminal vesicle. The obturator arises by a com mon stem with the umbilical the gluteals, descending leave the pelvis above and below the piriformis muscle. The inferior gluteal artery gives rise to the internal pudendal just before it leaves the pelvis.

The vessels are internal to the endopelvic fascin (Figs. 5 and 6)

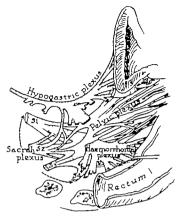

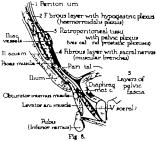

Fig 7. Dagram of the pelvic plents, showing origin and distribution of the chief components, and their gross interrelationships. Medial aspect. The hypogastric plenus is shown intact in its curving course to the originary bladder but has been cut away in that part which, overlying the pelvic plenus, contributes to the hemorrhoidal plenus between these two, and lateral to them, the fibers derived from the sacral nerves are shown streaming toward the bladder protate, and canal rectum, etc.

The endopelus fascia. The so-called endopeluse fascia is actually aponeurotic in nature. Con tinued upon the levator an and coccygeus muscles the endopeluse fascia becomes diaphragmatic fascia (Fig 6). Over the upper part of the obturn tor internus muscle it is parietal and when reflected from the peluic diaphragm to the rectum and bladder it becomes visceral (cf figures in Curtis Anson and Beaton, 1940).

It is clear then that the relations to fascial levels are of fundamental importance. In the heavy retropentoneal layer is located the large pelvic plexus, with its vesical and prostatic continuations (Fig 4) into this layer sink the originally superficial fibers of the inferior hypogastric plexus (Fig 2) and to it ascend the visceral rami originating from the sacral plexus of nerves (Figs. 3 to 5). In dissections this set of relationships is strikingly demonstrated when the heavy stratum is reflected (Fig 3) as they enter the pelvis from above the sympathetic fibers are situated just beneath the serous lavers and upon the heavy

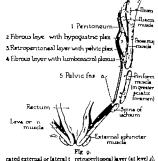

Figs. 8 and 9. Diagrams of the location of autonomic nerves, showing relations of the main sets to the subscrous strata of the pelvis. Coronal sections in anterior view. The chief elements of the broad pelvic plexus are lodged i the heavy layer of retroperitoneal tissue (at level a) hypogastric plexus and its subsidiaries are situated in thinner layer internal or medial thereto (level 2) while the sacral plexus and its fibers to pelvic musculature are lo-

retroperitoneal layer on the contrary the para sympathetics, originating behind, are located beneath the heavy layer and upon the endopelvic fascia as the latter covers the parietal musculature (obturator internus) All of the fibers from these two sources which ultimately reach the progenital organs enter and course through the heavy retropentoneal layer this would be the expected arrangement, since the strong fibrous layer be comes the immediate coat of each of the pelvic organs, merging with the sheath derived from the endopelvic fascla.

Sciatic foramen The sciatic foramen is bounded anteriorly by the arching border of the endopelvic fascus. Through it passes the superior gluteal, inferior gluteal, and internal pudendal ar teries, and the lumbosacral nerves which converge to form the sciatic. The parasympathetic nerves (nervus erigens) also visible, arise just before the sacral trunks som. The most caudal of the nerves arising from the sacral plexus is the nerve to the levator ani.

Ischiorectal fossa. The visceral rami derived from the excropudendal plexus are, then, promi nent as a group where they leave the sacral nerves at the arciform border of the sciatic foramen (Figs. s and 6) But, within the ischiorectal fossa, com parable fibers to the erectile bodies are difficult to segregate they tend to follow inconspicuously the pudendal nerve.

Posteriorly t the greater sciatic foramen its nerves ( t site of crosses in Figure 9) contributing chiefly t the for mation of the act tic nerve rest upon the fascial covering of the pinformis muscle

The ischial spine constitutes the serviceable landmark around it the obturator internus duappears as it leaves the pelvis attaching to the whial spine are the posterior end of the illococ cygeus part of the levator ani, and the lateral insertion of the coccypeus muscle which forms the posterior fourth of the pelvic diaphragm.

#### CONCLUSIONS

The autonomic nerves of the pelvis make up a set of neural sheets which not only are of gross dimensions, but which are of such position and form as to be demonstrable in the form of subpertoreal bands with predictable relationships to bony landmarks, to large blood vessels and to viscera. The large bands and the lesser contributory fibers as they course from root or plexus of origin to area of visceral termination, are either lodged within readily dissectable fibrous laminae or situated at levels either immediately superficual or deep to such laminae.

The chief layer is that which is most marked as it extends upward along the pelvic wall after hav ing formed a strong sheath for the urinary bladder and associated structures. It is the layer which transmits, also, the blood vessels of visceral supply Resting upon this stratum, at subperitoneal level, is an areolar tusine in which is situated most of the nerves of supply to the rectum under the same stratum are placed the sacropudendal plexus and the rami which pass therefrom to the large pleaus in the intermediate layer. The intermedial ate is therefore, the chief one of the three into the pelvic pleaus which it contains pass rami from the sympathetic and parasympathetic pleauses in layers on its internal and external aspects.

In the superficial (internal) layer of areolar tissue course the hypogastric plexus that portion of the pelvic plexus which sends ram chiefly to the rectum, the contributory mesenteric plexus, and the ductus deferens. These are structures which are subpentioneal or were originally mesenterial (when, embryonically a mesorectum existed) Being placed immediately beneath the serous lining of the pelvic cavity they elevate the peritoneum—but less markedly than do the umbilical ligaments (Fig. 1)

Topographically the infenor mesenteric plexus lies anterior to the ureter following it closely the infenor hypogastric plexus and its pelvic prolon gation he post-nor to the ureter between the latter and the rectum. The main mass of the plexus courses in a curving line—concave anteriorly—between the first piece of the sacrum and

the rectovesical fold

In its distal portion the fibers spread out principally on the superior surface of the bladder behind, groups of fibers radiate to the rectum a strong set forming a secondary plexus close to the rectal wall. Altogether these plexuses and derived fibers of visceral supply cover a semicircular area whose posterior boundary follows the contour of the rectum and that of the sacrum against which the latter rests (Fig. 2)

Embedded in the heavy layer of true retropen toneal tissue are the deeper elements of the autonomic supply (Fig 4) The anterior boundary of this set of fibers coincides with that of the more superficially situated hypogastric plexus, but its form is strikingly different. It assumes the configuration of a broad ribbon wider at the proximal and distal ends than in the middle twofourths of its extent Its widest portion is proxim ally situated, where visceral rams are contributed by the sacral nerves (Figs. 3 and 4) upon it converge, distally the fibers of the vesical portion of the pelvic plexus, to produce a second broadening terminal distribution to the bladder prostate, seminal vesicles and rectal ampulla is also instru mental in causing the widening of the band which occurs at its anteroinferior end. In an anteroposterior direction this intermediate band is somewhat more extensive than the superficial the former is carried to the sacrum (the points of origin of the nerves Fig 4) the latter to the rec tum (the visceral area of supply Fig 2) The intermediate band is the longer of the two owing to the fact that the greater bulk of its fibers are supplied, not to the rectum in the sacral curve, but to the bladder prostate, anal canal, as these rest upon the pelver floor

The third and deepest of the three neural strata is that composed of the proximal portions of the visceral rami of the pudendal plexus and the sa cral plexus, from which the rams are derived. Because the branches quickly enter the pelvic plexus-merging on the latter's deep aspect, and within the substance of the heavy retroperitonical tissue-this third layer is but slightly longer than it is wide. It overlies the second to fourth nerves (from which it arises) being thus caudally placed, its long axis is at almost a right angle to that of hypogastric plexus in the superficial, or first layer. The upper cords of the sacral plexus. and the lumbosacral cord from the abdominal level rest in similar tissue upon the piriformis muscle the pudendal rami leave the nerve trunks near the point where the latter emerge through the greater foramen en route to the gluteal region As the rami course toward the pelvic plexus, they come to lie upon the fascia covering the obturator internus.

The sympathetic fibers which descend into the pelvis from abdominal level form the mesenteric and hypogastric plexuses the parasympathetic fibers, commonly described as forming a nervus erigens, enter the pelvic plexus as a set of anastomotic nerves. All fibers, so far as gross examina tion reveals are mixed in the broad ribbon of nervous tissue which is termed pelvic plexus. Therefrom fibers stream toward the several pelvic organs, a degree of stratification obtaining in the distribution to mesenterial and to retroperitoneal viscera for the most part nerves to the rectum pass, on immediately subperstoned or superficial, level, from the anterior border of the plexus back ward in radiating fashion to the pelvic portion of the digestive tube similarly nerves to the urinary bladder subjacent prostate gland to the seminal vesicles, lodged, at the intermediate level in the heavy sheath of retroperatoneal tissue stream downward and forward to the organs named-all ultimately supported by the funnelshaped pelvic diaphraem

From the surgical standpoint the following conclusions seem warranted sympathetic fibers may be transected by presacral neurectomy para sympathetic elements left untouched by the same procedure in both abdominal and perineal approach to the rectum (in high operation for car chroma) the chief portions of the autonomic plex uses are removed by safe distance, from the

surgical field—being parietal in position in the dorsal portion of the pelvic cavity in any of the regular approaches (puble, transsymphysial penneal or rectal) to the urmary bladder or prostate gland the disturbance of tissue would occur in areas where concentration of autonomic fibers is minimal—behind the main plexiform aggregations in anterior approach, and above them in inferior entrance to the pelvis. However in wide removal of carcinomatous lymphatic and associated fibrous tissue within the pelvis, the areas where nerves are abundant would be affected the plexuses, in resting upon the hypogastric artery and its important branches, are situated between the peritoneum and the lymphatics, since the latter are closely associated with the blood vessels.

In summary then, it may be said that the nerves of supply to the pelvic organs are so disposed as to be naturally protected from damage in urological surgery. In spreading out upon the bladder from behind and above, terminal fibers are fewest on the anterior (apical) and inferolateral portions in supplying the rectal and anal parts of the canal the nerves do not descend with the tube in the form of an investing net, but, approaching the canal from the side they end in relation to local

segments. Finally it may be pointed out that so great is the intermingling within the plexus of fibers derived from various sources that localized excision or extirpation would be expected to result In relatively slight interference with function of a pelvic organ

# STUDIES ON EXOPHTHALMOS PRODUCED BY THYROTROPIC HORMONE

Changes Induced in Various Tissues and Organs (Including the Orbit) by Thyrotropic Hormone and Their Relationship to Exophthalmos

BROWN M DOBYNS M D., Rochester Minnesota

N a preceding publication (21) the development of exophthalmos in thyroidectomized animals receiving various preparations of thyrotropic hormone was described tuitrin T produced a striking degree of exoph thalmos but in many animals it also produced profound myasthenia and loss of weight in spite of the absence of the thyroid A so called purified preparation however failed to produce exoph thalmos toxic manifestations or loss of weight but did cause some hyperplasm of the thyroid of intact animals. A crude thyrotropic preparation which was prepared in a manner similar to that of the so called purified preparation but without the additional efforts at purification and which was administered in quantities equal in thyroid stimulating effect to the purified product caused exophthalmos. This exophthalmos, however, was less striking than that produced by antuitrin T Toxic effects and loss of weight from the crude preparation were minimal. The specific metabolic principle, a fraction of thyrotropic hormone did not produce exophthalmos and was known from the work of others (8 18 19) not to produce thyroid hyperplasia

The tissues of these animals, from which ac curate data on exophthalmos have been obtained have furnished the source of material for this report

## LITERATURE

In 1936 Smelser (43) described an infiltration of a stainable material accompanied by nests of lymphocytes and edema in the extraocular muscles and orbital fat of guinea pigs rendered exophthalmic by thyrotropic hormone This was confirmed by Paulson (37,39) who also described loss of striations in the extraocular muscles. Smelser (44,46) concluded in later papers that the changes in muscle were confined to the connective

Abrikament of thesis submitted by Dr. Dodynes to the Freutly of the Graduate School of the Investry of Minneyer in reartial fulfillment of the requirements for the degree of Ph.D. in Surgery Work done t the Institt of Experimental Medicine, in the Intonatory of Dr. George M. Higgins.

Dr. Dodyna, I low in Sergery M. y. T. undation.

tissue between the muscle fibers. Paulson (38 30) later found muscle degeneration and round cell infiltration in cardiac and other skeletal muscles He reported that this change was most striking in the first few days of administration of thyrotropic hormone and that it occurred repartless of the presence or absence of the thyroid cellular reaction was found to a much milder de gree in normal and thyroidectomized control anımals.

Aird (12) demonstrated varying degrees of cellular reaction in extraocular muscles and edema of orbital tissue with several thyrotropic prepara tions Brock (13) although primarily interested in cellular infiltration in cervical sympathetic gan glia mentioned the feature in muscle. Smelser (44) and Paulson (37) reported that the muscle changes might not be present although exoph thalmos developed. Paulson (38) could not de monstrate an appreciable increase of the water content of muscles but in agreement with Smelser (44 47) he did show an increase of the water content and volume of the orbital tissue mass.

Smelser (45) after finding an edematous in filtration in the connective tissue of fat in the orbit studied other fat depots. Cervical and axillary fat were unaffected but the fat about the kidneys, ovaries and ureters appeared to be in volved by the same process although to a much less striking degree than in the orbit. These observations on fat depots other than the orbit have not been confirmed Since the investigation described in this publication was carried out Smelser (47) has described an increase of the residue of the orbital tissues after the extraction of fats and water in animals that have been given thyrotropic hormone

The significance of the cellular reaction elicited by thyrotropic hormone in fat connective tissue and muscle is not understood. Just what the relationship of these tissue changes may be to the exophthalmos that develops is not certain. A cellular reaction accompanied by edema and fibrosis in orbital tissues of patients suffering from

Fig. 1 Left, perhaphric fat from normal control guinea pig. Right, perhaphric fat f om guinea pig treated with antuitin T. Note th apparent replacement of opage fat by a more transparent gelatinous material (transillumina

malignant exophthelmos has been described by Naffziger and many others (ii 12 13 17 22 23 273,13,33,35,43,44,48). It may be of interest that Haik (27) recently reported extreme fatty metamorphosas of the liver' and cloudy swelling in the kidney in a case of malignant exophthalmos at necropsy. Naffziger (34) reporting on muscle biopases from locations other than the orbit, did not observe the muscle changes usually en countered in the orbit.

#### EXPERIMENTS PRELIMINARY TO THIS STUDY

In preliminary experiments, examination of insues of animals receiving antuitina T confirmed these reports of the presence of round cells in orbital tissue, to a lesser degree in muscles, and in many of the fat depots throughout the body. In other preliminary studies it was found that these cells contained many fine droplets of fat. Likewise muscle fibers throughout the body and the cells of the liver and the kidneys were leaded with fat droplets after thyrotropic hormone had been administered.

#### PURPOSE OF THIS STUDY

The purpose of this study was to investigate the possibility of a general systemic cellular reaction in gulnes pag siven anturin T and to correlate these reactions with those known to occur in the orbit associated with exophibalinos. In addition observations were made of the reactions which ensued in animals when they were given various other crude and so called purified thyrotropic preparations. Since the unit potencies of these preparations differed from that of anturin T

any comparison of their effectiveness with that of antuitrin T was not undertaken.

#### METHODS

The several groups of animals that had re ceived various thyrotropic preparations for varying lengths of time were as follows

A. Antultum T was administered in daily amounts containing 25 Junkmann-Schoeller untilto 15 thyroldectomized animals, 7 of which had also been orchectomized. Four intact animals also received this product. The period of adminism tion was from 3 to 32 days.

B The solvent for antuitrin T including the preservative but without the pituitary ingredient, was given in comparable daily doses as a control

to a intact animals.

C Five intact animals with comparable body weights were fasted, to induce a loss of weight like that sustained by some of the animals receiving antutrin T. These served as controls for changes sustained solely from loss of body weight.

onanges sustained solely from loss of body weight.

D A so called purified thyrotropic factor was given to 8 thyroidectomized animals in dally amounts containing 2 5 5,0, and 10 0 Rowland-Parkes units for periods of from 7 to 30 days.

E. Crude thyrotropic preparation was given in daily amounts containing 5 and 10 Rowlands-Parkes units to 10 thyroidectomized animals for periods of from 8 to 24 days.

F The specific metabolic principle, which is a fraction of a thyrotropic preparation and which failed to produce thyroid hyperplain was administered in daily amounts of a cubic centimeter (later raised to a cubic centimeters) to 4 the rodectomized animals for periods of 6 to 8 days.

Most of the animals were killed by ether. As a control procedure, a few animals were killed by elthal does of pentoberital sodium. Arillary cervical periureteral, orbital and testroular fair and temporal, cardiae, and extraocular muscles were removed and fixed in 10 per cent solution of formalin. The entire orbital contents were discreted from the bony orbit as a single unit. This mass of tissue was fixed and sections were made through the entire substance just posterior to the globe so that a cross section of all retrobulbar tissues was obtained. Sections were made of the liver kidney spileen and representative lymph.

A unit so that amount of harmone which, injected duly for three days, causes in oil namels (st. sa), recognized hypertraphy of the sylthetims and deeppearance of cellular in the thyrotoc layers play to be so yet in acquire (Potsocy as based on namely by manifesterer).

nodes. In some animals sections of the ureter and of the small intestine were prepared

Two techniques for histologic preparation were employed. Frozen sections were cut and stained with scarlet red and counterstained with hema toxylin. Paraffin sections were stained with the routine hematoxylin and cosin stains. In in stainces in which connective tissue changes were observed. Mallor, Heidenhain and van Gieson stains were applied. In some instances mucicar mine stains were used.

At the time of thyroidectomy and orchectomy biopsies were taken of cervical and testicular fat. These tissues were subsequently contrasted with those obtained from the same animals after thyrotropic hormone had been given to them

The changes in each tissue were studied and recorded by grading the degree of change on the basis of 1 to 4 (1 being the smallest discernible change and 4 being the most striking degree of change)

A Gross changes induced in tissues by thyrotropic hormone preparations. Antultrin T produced the most striking gross changes in animals regardless of the presence or absence of the thy roid. Fat from most of the fat depots had a redder appearance and possessed a more firm and rubbery consistency than did fat of normal animals. This gross change was most striking in the first few days of administration of antultrin T After longer periods the fat depots were extremely depleted of fat and, in the place of the fat there was found a translucent gelatinous material (Fig. 1). The most striking changes in fat occurred in animals which had lost the most

weight. Although some of the animals treated with antuitin T had lost considerable weight in many cases the volume of the gelatinous fat depots was not materially decreased. This was in contrast to the markedly decreased volume of the fat depots of the fasted control animals which had lost comparable amounts of weight. In the fasted guinea pigs which had lost considerable weight and possessed depleted fat depots, the fat remained soft and showed little if any of the gelatinous character. The fat in animals which were given the preparations, other than antuitin T did not differ grossly, from the normal

In animals which had received antutrin T for only a few days the skeletal muscles were rather pale and had a tendency to tear easily when stretched The livers of such animals were extremely pale alightly enlarged and very frable But after more prolonged administration of antuitrin T the skeletal muscles and liver returned to a more normal color and consistency Color changes similar to those in the liver were induced in the kidneys.

In the animals given antuitrin T the connective tissue septa of the harderian glands were edema tous and appeared as dark partitions between the lobules, much m contrast to these septa in normal glands.

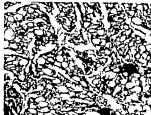

In the animals which received the crude thyrotropic preparation the connective tissue sepin of the harderian glands were less edematous than those in animals receiving antiutini T. In certain of this group which gained less weight the livers were rather pale and mottled and the fat depots were abundant occasionally more glossy and edematous than normal.

Fig. 4. a, left, Axillary fat of normal guinea pig. b, Changes induced i the axillary fat of a thyroidectomized

The tissues of the animals which received the solvent for antuitrin T and of those which received the so called purified thyrotropic factor or the specific metabolic principle did not show any of these gross changes such as occurred in the animals receiving antuitrin T or the crude thyrotropic preparation

B Microscopic changes induced in tissues of animals receiving anisativin T. The most consistent change observed in the tissues of animals receiving antiurin T was the appearance of large numbers of mononuclear and polymorphonuclear leucocytes containing fat droplets a condition not ordinarily seem in such cells of control animals. This cellular reaction was accompanied by varying degrees of edema. These fat-containing cells occurred not only in the orbital tissue but throughout the connective tissue generally. Fat tissues throughout the body were markedly

uinea pag by 0.5 cubic centimeter of antuitrin T daily or 3 days (hematoxyli and cost × 18)

altered (Figs. 2 3 4, and 5) The thin septa of connective tissue fibers between the fat cells were three to four times their normal thickness. Clusters of large and small motonuclear and polymorphonuclear leucocytes had infiltrated into these thickness expias. In some areas where the reaction was extreme, a homogeneous, faintly staining material had formed within these con nective tissue spaces to such an extent that the fat cells appeared to be floating in a matrix (Figs. 2 and 4). This cellular reaction resembled very closely the hutlogic pattern of the reparative processes seen in fat necrosis accompanying traumatized tissue.

In animals given antuitin T for short periods, there were more polymorphonuclear cells con taining more fat disoplets and there was more edema but only slight proliferation of connective tissue. In animals given this preparation for

Fig 5 a, left, Orbital f t of normal guines pig b, Changes induced i the orbital fat of thyroidectomized

guinea pig by 0.5 cubic centimeter of antuitri T dall for 9 days (bematoxylin and cosi × 8)

Fig 6 Fat laden skeletal (temporal) muscle fibers of an intact guinea pg that had received 0.5 cubic centimeter of antimetin T daily for 2 days (scarlet red and alum hema toxylin ×56)

longer periods, there were fewer polymorphonu dear cells more lymphocytes, more large macrophages and fibroblasts and more collagenous connective tissue but less edema

In sections of the cardiac and skeletal muscles of injected animals there was but little cellular infiltration although there was more than in sections of normal muscle. In preparations stained with hematoxylin and eosin a mild degenerative process of muscle fibers characterized by a loss of atriations and a granular appearance of the fibers, was evident. This occurred in a spotty manner without apparent relation to the blood supply or to any other recognized anatomic feature.

These changes in muscle took on added sig nificance when fat stains were applied to these same muscles for it was found that the fibers, in the same spotty fashion were loaded with tiny droplets of fat (Fig 6) In some sections of a single fiber the fat was in great abundance while in other places along the same fiber relatively little change from the normal was found. The degree of change in various muscles in the same animal showed considerable variation. The extra ocular muscles when studied in this way were almost always found to contain more fat than any other muscles. At times the lymphocytes and the large macrophages were more abundant about those portions of the muscle containing the most fat however in other instances the most affected muscles contained no new cellular elements. These macrophages and lymphocytes were always most abundant in connective tissue border ing muscle fibers or in perivascular locations

Fig. 7. a, left, Normal harderian gland (×35) b, Marked edema of the connective tissue around and within the harderian gland of a thyroidectomized guinea pig in which exophthalmos had been induced by administration of antitrin T (×35)

The same general trend of the reaction that was observed in connective tissue and fat namely less fat in tissue macrophages as treatment continued, occurred also in muscle tissue. Animals treated for a short time contained much more fat in the muscle fibers than those treated for longer periods. A very close correlation was noted be tween the presence of fat in the muscle fibers and the degree of myasthenia produced by antuitrin T. This correlation held true even in the animals.

I sg. 8. Edema in skeletal (temporal) muscle following the administration fo op cubic continuers of annitrin T dally for 13 days to a thyrodectomized gu nea pix (hema tory)\* and covin X140). This is an example of a striking degree of edema in muscle. There was rather high grade edema of connective tissue (see Figs. 9 and 4) through out the body of this animal as well as marked exophthal most. The temporal muscle was chosen because by its position edema is least likely to develop on the had of dependency.

treated for longer periods when fat in muscle was rarely found and myasthenia was infrequently observed.

The large, pale, friable livers observed in the animals receiving antuitrin T for a short time contained relatively large amounts of fat but the livers of those animals given the preparation for longer periods contained less fat. In those animals in which the kidney was studied the droplets of fat were present in cells of the tubular epithelium. However here again the amount of fat present was readily correlated with the duration of the injections and corresponded well with the presence of fat in muscle and in liver Fat droplets were seen too in the large reticuloendothelial cells of the lung in the spleen and in lymph nodes of animals which possessed pronounced changes in fat elsewhere in the body. Likewise the epithelml cells of the ileum and bronchs contained tiny droplets of fat in their cytoplasm. Excessive quantities of fat were found in the lacteals of the small intestine.

Edems in the orbit was most easily recognized in the septa of the harderian glands (Fig. 7). It was present, too in the connective tissue of the fat in the orbit (Fig. 5) and in other fat depots of the body (Fig. 3). In a few animals which had had striking exophthalmos, extensive edema had developed in the temporal muscle (Fig. 8). In many animals edema was either present in small

amounts or absent entirely from these muscles. The infiltration of a homogeneous, faintly staming intercellular substance in connective tissue especially in adipose tissue, appeared unite consistently not only in the orbit but elsewhere in the body (Figs. 2 3 4, and 5) Muckar mine stams did not reveal the presence of mucin but van Greson and Mallory Heidenham tech niques indicated that this material was probably collagen of young connective tissue. This homogeneous material was associated with the cellular reaction described previously and was usually most prevalent after a period of treatment when the acute phase of the cellular reaction was subsiding. The effect of antuitrin T on the tissues of intact animals is the same as seen in thyroidectomized animals when one considers equal periods of treatment. The general impression was that the edema that developed in normal animals was somewhat less than that in thyroklectomized anunals.

The tissues of the group of animals which received the solvent for antuitrin T did not sustain these histologic changes. This, therefore would seem to eliminate the possibility that the solvent or preservative was the causative factor in producing the tissue changes. Exophthalmos, it will be recalled did not develop in this group of animals.

Because the most striking changes in fat or curred during the early administration of an tuitin T and because it was during this period that the animals lost the most weight it seemed advisable to know whether phagocytosis of fat occurred in animals which lost weight rapidly for other reasons, for example, fasting. It is known that feating is accompanied by a rapid mobilize tion of fat from depots and that this fat is subsequently found in abundance in the liver.

In the fat depots of fasted animals, in which the fat was extremely depleted nuclei of fat cells per sisted and there was a relative increase of connective tissue with few lymphocytes, macrophages, and polymorphonuclear leucocytes. Fat droplets were occasionally seen in these cells but in neg ligible amounts when the fasted animals were compared with animals which had received antutrin T in no instance was this finding more than minimal in the fat depots of fasted animals.

The presence of fat in muscles was also found in fat-stained preparations from fasted animals but to a very mild degree. There was also a slight amount of edema in the connective tissue of some of the fasted animals.

It has been shown by the author in experiments described elsewhere (ro) that thyroidectomy alone was not followed by any appreciable in crease of cellular elements or edema in connective tissue

C Microscopic changes induced in the tissues by other thyrotropic preparations. The purified thyrotropic factor in the amounts administered, re sulted in the appearance of some fat in the liver but no increase of cellular elements in connective tissue was recognized and phagocytods of fat by such cells was not graded more than I In the hematoxylm and eosin preparations there was some evidence of an increase of the number of macrophages but the deposition of new connective tissue was not demonstrable. Muscle degenera tion however occurred to an appreciable degree (grade 3) in only one animal, which was an exception and in which some exophthalmos bad developed. Edema in all tissues including the orbit was more noticeable than in thyroidectomized controls, and a very slight increase in connective turne had been induced.

Generally speaking the tissue reaction in the animals given the crude thyrotropic preparation in the amounts indicated was less pronounced than that found in animals given antuitin T However it was more marked than the equivocal

changes induced by the so called purified thyro-tropic preparation The degree of edema in these DOBANZ animals resembled that of animals treated with antuitrin T and occurred throughout all the connective tissues examined There was an abnormal increase of the number of tissue macrophages but polymorphonuclear cells were rarely seen. The presence of fat droplets in tissue mac rophages, however was considerably less than in animals given antuitfin T In only about a half of the animals such intracellular fat was not demonstrable however it was relatively marked in a few animals which had gained less weight. The appearance of fat droplets in muscle fibers was moderate in most animals. It was not demonstrable at all in one animal which was not conspicuously different in other respects. The abnormal presence of fat in other organs was vanable and the homogeneous faint staining material was not found in these animals

In animals which received the crude thyrotropic preparation in the amounts indicated less striking exophthalmos developed than in animals treated with antuitrin T Edema of connective tissue was a prominent feature but the cellular reaction associated with the abnormal presence of fat in many locations and the deposition of con nective these was not as striking. The shortest period of observation of the animals was 8 days and on the average these animals were observed longer than were those given antuitin T. The experience with antiutrin T has shown that the acute phase of the reaction occurred early in the course of administration of thyrotropic hormone. The presence of moderate numbers of mononu chear cells in the tissue of animals treated for longer periods with the crude thyrotropic preparation may bear witness to a more acute re-

The traces of the animals which had received action that had preceded the specific metabolic principle in the amounts indicated were of interest because in most instances they appeared to be unchanged One animal which had lost some weight because of apparent toxicity of the product had a grade 3 edema in the orbit but this was not found in other tissues, and the animal had not become exophthal mic. In some animals very small amounts of fat were demonstrated in muscle fibers

This report is specifically concerned with certain changes which were observed in the orbit and in various other regions and organs of guines page and which ensued on the administration of antutrin T for varying periods. In addition, it

comparable animals on the administration of certain other preparations including the solvent for antuitrin T a crude, and a so called purified thyrotropic preparation the potencies of which had been assayed in terms of units not comparable to those of antuitrin T Since antuitrin T was assayed on the basis of one type of unit and the crude and purified preparations were assayed on the basis of another type of unit, it is not possible to compare the effectiveness of these preparations with that of antuitrin T on the basis of unit It is however, possible to relate the exophthalmos to the tissue changes in any one animal or in any group of animals, irrespective of the preparation which produced the changes

As hitherto shown (21) antuirin T produced marked exophthalmos. The crude thyrotropic preparation in the amounts administered was less effective and the purified thyrotropic prepara tion in the amounts given was least effective of all in producing exophthalmos. The degree of cellular reaction the edema and the connective tissue changes which occurred in these three groups of animals were most marked in those receiving antuitrin T less so in those receiving the crude preparation and least so in those receiving the so called purified product.

This study has shown that a general systemic alteration in fat depots occurred in animals which anciscon in las octores occurses in annuals which received antuitrin T These depots were rapidly depleted of their fat contents, which were replaced by a more translucent gelatinous material. These changes were associated with the infiltration of large numbers of polymorphonuclear leucocytes large numbers of polynauphonuciear redocytes and tissue macrophages which were loaded with tiny fat droplets. The impression was gained that these large macrophages had phagocytosed fat and were transforming into fibroblasts still con taining fat, and ultimately gave rise to connective tissue fibers Much edema was associated with this reaction Further evidence of the changes in the fat of the bod) was shown by the appearance of large amounts of fat in the liver kinney and skeletal and cardiac muscle and in the epithern of bronchus, ureter, and the ileum

It is probably of considerable clinical in that a relationship was recognized between appearance of fat in the skeletal muscles z.r. profound myasthenia that developed in z mag protound after antultrin T was given. cellular reactions as well as exophilater of curred in animals regardless of the present absence of the thyroid or the term ansence of the specific of animals in which there was the appearance of animais in abnormal quantities in the foregard droplets of fat were also observed in the reticuloendothelial cells of the lungs, lymph nodes, and spleen. It would seem that the appearance of fat in these specialized cells constitutes a part of the same generalized systemic reaction throughout the body. The results of these experiments sug gest that there is a generalized afteration of fat metabolism and that the connective tissue reaction and the exophthalmos may be associated

with it. These observations confirm the opinion of Smelser (45) that tissue reactions may occur in other locations than the orbit. The degeneration of skeletal muscle fibers, illustrated with the hematoxylin and eosin preparations described by Paulson (37) was apparently due to the presence of fat in these muscle fibers. Whether the lymphocytes and macrophages in muscle described by him as well as others are present to remove the fat or to carry away products of cellular de-

generation is unknown.

The demonstration of these cytologic changes in tissues, resulting in the ultimate deposition of connective tusue in the involved regions, supports the opinion of Friedgood (24 26) and Aird (1 2) that exophthalmos, after being maintained for a period, becomes irreversible. This also supports the observation of Smelser (47) that there is an increase of the residue which remains after the extraction of water and fat from orbital tissues of animals treated with thyrotropic hormone.

It is well known that pituitary extracts cause an increase of liver fat (3 7 10,30) Barrett, Best, and Ridout (s) showed by labeling fat molecules that fat was transferred from the various denots to the liver But the possible relation of this observation on the liver to conditions which incite exophthalmos has not been suggested

Several terms have been given to unlaolated substances in the anterior pituitary which in fluence the mobilization of fat, but their chemical relationship or similarity to the substances which stimulate the thyroid gland is uncertain.

The fact that fasted animals show some of these tissue changes, especially those relating to fat metabolism, confuses somewhat an inter pretation of the mechanism of such reactions to antuitrin T The changes produced by the hor mone are not identical with those induced by fasting Furthermore, they are far more extreme than those seen in the fat depots of fasting animals. It has been pointed out (21) that thyrotropic hormone had toxic effects on animals even before the thyroid response was fully elicited. It is known that animals, when given thyrotropic bormone do not withstand surgical procedures well (14) In a similar manner fasting animals (40) or animals recovering from surgical procedures (21) do not well withstand the administration of thyrotropic hormone.

The observations of increased fat in the enithelium and lacteals of the small bowel of these animals receiving antuitrin T may have some relation to the observation of Rony and his associates, who found an increase of fat in the lacteals of fasted animals. In a similar way the observation by Binet and his associates of fat globules in the bronchial epithelium and round cells of the lung in fasting animals is recalled by these observations, which show the presence of fat in the bronchial epithelium of animals receiving thyrotropic hormone.

It is quite possible that there may be some relationship between the myasthenia produced in these animals and the myasthenia in exophthalmic goiter Plummer and Wilder found a positive correlation between the loss of quadriceps strength and the exophthalmos in exophthalmic golter. These systemic changes may in some way be related to the exophthalmos and to the myasthen is produced in animals by administration of antwittin T

#### SUMMARY

Tissues of animals which during life had been given various thyrotropic bormone preparations and on which very accurate records of the development of exophthalmos had been made were studied grossly and by several histologic tech nimes.

Antuitrin T which produced the most striking exophthalmos was found to produce gross and microscopic changes in connective tierne not only in the orbit but elsewhere in the body

The study showed that as a result of the administration of thyrotropic hormone there was a generalized alteration in fat depots, which are rapidly depleted of their fat contents and are replaced by a more translucent gelatinous ma terial. Histologically these changes in fat and connective tissue are characterized by the presence of edema and the infiltration of large numbers of polymorphonuclear leucocytes, lymphocytes, and tissue macrophages. Early in the reaction the polymorphonuclear leucocytes and tissue macrophages are loaded with tiny droplets of fat. Later an increase of new connective tissue is evident. This reaction was correlated with the exophthalmos which had previously developed in these animals.

Skeletal and cardiac muscle fibers during the early period of administration of thyrotropic

# DOBYNS STUDIES ON EXOPHTHALMOS FROM THYROTROLLO

hormone lost their structions and were found to contain multitudes of they fat droplets which lined up in a pattern representing the crossstrictions of the fibers. New cellular elements were present among muscle fibers Considerable significance was attributed to a close correlation between the presence of fat in the muscles and the myasthenia present in these animals before death

a fact which may have clinical correlations Further evidence of alterations in fat during the early administration of thyrotropic hormone is the presence of large amounts of fat in the liver kidneys and epithelium from several locations, as well as large phagocytic cells of the lungs spleen

These changes took place regardless of the and lymph nodes presence or absence of the thyrold

### THE USE OF COMPRESSION IN THE TREATMENT OF INJURIES

THE use of compression to arrest and prevent escape of blood and serum into body tissues represents a surgical principle which, to use Homans words, has been 'perennially discovered discredited forgotten, rediscovered and reaffirmed

The subcutaneous rupture of blood vessels and the rapid escape of blood and serum into soft tissues are of frequent and everyday occurrence The blow over the eye or fore head, the crushing of a finger tip the twist of an ankle—all lead to rapidly forming swelling and the subsequent discoloration that in dicate blood vessels have been torn and blood has infiltrated the surrounding tissues. Severe contusions and crushing injuries of soft tissue and bone are followed by the same train of events in a more exaggerated form

When one is confronted with an open wound from which active bleeding is taking

place one a first instinct—whether layman or surgeon-is to apply pressure to stop the bleeding The surgeon in the operating room almost dally instinctively and logically presses gauze sponges or 'laparotomy pada'' against a bleeding surface to arrest coming The same principle can be employed, and with almost equal effectiveness in the control of bleeding which does not meet the eye as a rapidly welling pool of blood but which is accumulating under the surface in direct ratio to the extent of injury and the elasticity of the overlying tissues.

When one recalls what happens when a considerable quantity of blood infiltrates soft tissues-the harmful compression of fragile living cells the slow disintegration of red cells the fibrosis that follows the absorption of serum and disintegrated corpuscies—it be comes a matter both of logical treatment and of importance to arrest such bleeding as promptly as possible. When one recalls further that after an extensive crushing injury the loss of blood into the soft tissues can be so great as to lead to shock and threaten life, the arrest of such hemorrhage becomes a matter of life and death. The most certain means at our command of controlling such bleeding is by amooth firm compression of the affected area

There is a second important group of cases in which similar conditions obtain—those in which blood without red cells escapes rapidly into the surrounding tissues and leads to the same local and general symptoms of swelling distention of tissues and fluid loss. Whatever the cause of the fluid loss that rapidly follows exposure to extremes of heat and cold-in creased permeability of damaged capillaries,

EDITORIAL 619

local vasodilator reaction which causes the region (surrounding a burn) to become an open abunt with capacity to contain a maximal amount of intravascular blood 1 or whether still other factors at work-every worker interested in the treatment of burns or of injuries due to freezing has been con cerned with the rapid loss of fluid into the tissues and with the serious effect of such loss both on the tissues at the site of injury and on the entire body mechanism. With the con centrated attention that has been given to these injuries in recent years it has become increasingly apparent that the prompt application of pressure over the injured area is the most certain and effective means of preventing and checking fluid loss and of arresting the 'white hemorrhage which is so important a factor in the clinical picture that develops rapidly after severe injuries due to extreme heat and cold.

A third group of cases in which the use of compression is an important factor in bringing about recovery is well illustrated by a simple case report from Sampson Gamgee's Surgical Lectures published in 1883.

On the 18th September 1879 a bloated middleaged man came before me in the out patient room with his right leg big tense purple, and exquisitely tender

"The man had earned his living as a hawker and had been a hard drinker On admission the right leg was of greatly increased size, and of deep purple colour the skin tense and shining and intensely sensitive to the alightest touch. Circular measure ment of the two legs gave the following result

At the middle of the patella 18% inches 17 forches Six inches below 18 faches 7 inches Round the malleoil 14 inches 1 18 inches

Placing the man on his back and raising the foot I enveloped the limb in a layer of cotton wool, over which I constructed a compressing millboard and bandage latticework.

"September 19th, 9 a.m.—After the lapse of 13 hours bandages very loose from the considerable

subaidence of swelling which has taken place in the twelve hours since they were applied. I applied another bandage with firmer pressure and suspended the limb. The patient had passed a comfortable night, with the exception of some pain between midnight and 5 a.m. He is now perfectly comfortable.

8 15 p.m.—Has been very easy all day On removing the apparatus the limb is much paler and softer and scarcely tender on pressure. The patients spontaneous expression is It is wonderful how I can bear it handled now and I could not stand a feather touching it last night. The following are the circular measurements of the right leg:

And patella 17 inches 134 inches Skr inches below 1514 inches 134 inches Round the maileoli. 13 inches 2 inches 2 inches

The strips of pasteboard were now re moistened, to fit the shrunken limb and bandaged to it, latticework fashion, over cotton wool with increased pressure. The application last night though conducted most gently caused occasional exclamations of intense suffering but the patient bere it tonight, though executed comparatively roughly without the least pain. The same process was repeated daily to follow up the decreasing limb with equable pressure and at the end of a week, the two legs were of equal size.

Admitting the beneficial influence of the hori sontal position of the body and of the suspension of the limb in the flexed position, there can be no question that the immediate relief of pain and the rapid subsidence of swelling were chiefly due to smooth elastic pressure"

Gamgee cites a number of similar cases in which disabilities resulting from widespread exudation through the soft tissues associated with a chronic inflammatory process responded rapidly to the application of compression and immobilizing splints. Further more he points out that many English French, and German writers during the century preceding had repeatedly emphasized the importance of compression in the treat ment of injuries and of chronic inflammation -a method "forgotten rediscovered and reaffirmed Ironically perhaps, Gamgee obtained such good results by adhering to sound surgical principles that he was reluctant to accept the teachings of his friend and classmate Lister

It seems almost superfluous to repeat in a surgical journal Blair's emphasis on "The
